TITLE: Doconce: Document Once, Include Anywhere

AUTHOR: Hans Petter Langtangen at Simula Research Laboratory and University of O

slo

DATE: today

* When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?

* Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like "LaTeX": "http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf", "HTML": "http://www.htmlcodetutorial.com/", "reStructuredText": "http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html", "Sphinx": "http://sphinx.pocoo.org/contents.html", and "wiki": "http://code.google.com/p/support/wiki/WikiSyntax"? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

* Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

===== The Doconce Concept ======

#include "_what_is.do.txt"

====== What Does Doconce Look Like? ======

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- * Bullet lists arise from lines starting with an asterisk.
- * *Emphasized words* are surrounded by asterisks.
- * _Words in boldface_ are surrounded by underscores.
- * Words from computer code are enclosed in back quotes and then typeset 'verbatim (in a monospace font)'.
- * Section headings are recognied by equality ('=') signs before and after the title, and the number of '=' signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- * Paragraph headings are recognized by a double underscore before and after the heading.

,,

- * The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- * Blocks of computer code can easily be included by placing '!bc' (begin code) and '!ec' (end code) commands at separate lines before and after the code block.
- * Blocks of computer code can also be imported from source files.
- * Blocks of LaTeX mathematics can easily be included by placing '!bt' (begin TeX) and '!et' (end TeX) commands at separate lines before and after the math block.
- * There is support for both LaTeX and text-like inline mathematics.
- * Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- * Invisible comments in the output format can be inserted throughout the text.
- * Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- * There is special support for advanced exercises features.
- * With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- * With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

==== A Subsection with Sample Text =====
label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to

Section ref{my:first:sec}.

Doconce also allows inline comments of the form [name: comment] (with a space after 'name:'), e.g., such as [hpl: here I will make some remarks to the text]. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
		·

lines beginning with # are comment lines

The Doconce text above results in the following little document:

==== A Subsection with Sample Text ===== label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have numbered items instead of bullets, just use an 'o' (for ordered) instead of the asterisk:

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01

,

```
tutorial.do.txt
    2.0
          1.376512
                     11.919
    4.0
          1.1E + 1
                     14.717624
==== Mathematics and Computer Code =====
Inline mathematics, such as \ln = \sin(x), v = \sin(x),
allows the formula to be specified both as LaTeX and as plain text.
This results in a professional LaTeX typesetting, but in other formats
the text version normally looks better than raw LaTeX mathematics with
backslashes. An inline formula like \ln = \sin(x) is
typeset as
\ln = \sin(x) v = \sin(x)
!ec
The pipe symbol acts as a delimiter between LaTeX code and the plain text
version of the formula. If you write a lot of mathematics, only the
output formats 'latex', 'pdflatex', 'html', 'sphinx', and 'pandoc'
are of interest
and all these support inline LaTeX mathematics so then you will naturally
drop the pipe symbol and write just
!bc
\ln = \sin(x)
lec.
However, if you want more textual formats, like plain text or reStructuredText,
the text after the pipe symbol may help to make the math formula more readable
if there are backslahes or other special LaTeX symbols in the LaTeX code.
Blocks of mathematics are better typeset with raw LaTeX, inside
'!bt' and '!et' (begin tex / end tex) instructions.
The result looks like this:
!bt
\begin{align}
{\partial v\over\partial t} &= \nabla\cdot(q(u)\nabla v) + g
\end{align}
Of course, such blocks only looks nice in formats with support
for LaTeX mathematics, and here the align environment in particular
(this includes 'latex', 'pdflatex', 'html', and 'sphinx'). The raw
LaTeX syntax appears in simpler formats, but can still be useful
for those who can read LaTeX syntax.
You can have blocks of computer code, starting and ending with
'!bc' and '!ec' instructions, respectively. Such blocks are formatted as
!bc cod
from math import sin, pi
def myfunc(x):
   return sin(pi*x)
import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
A code block must come after some plain sentence (at least for successful
output to 'sphinx', 'rst', and ASCII-close formats),
```

not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., '!bc xxx' where 'xxx' is an identifier like 'pycod' for code snippet in Python, 'sys' for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in 'ptex2tex' and defined in a configuration file '.ptext2tex.cfg', while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, 'pro' and 'cod' are 'python', 'sys' is 'console', while 'xpro' and 'xcod' are computer language specific for 'x' in 'f' (Fortran), 'c' (C), 'cpp' (C++), 'pl' (Perl), 'm' (Matlab), 'sh' (Unix shells), 'cy' (Cython), and 'py' (Python).

(Any sphinx code-block comment, whether inside verbatim code
blocks or outside, yields a mapping between bc arguments
and computer languages. In case of muliple definitions, the
first one is used.)

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with '!bc pro', while a part of a file is copied into a '!bc cod' environment. What 'pro' and 'cod' mean is then defined through a '.ptex2tex.cfg' file for LaTeX and a 'sphinx code-blocks' comment for Sphinx.

Another document can be included by writing '#include "mynote.do.txt"' on a line starting with (another) hash sign. Doconce documents have extension 'do.txt'. The 'do' part stands for doconce, while the trailing '.txt' denotes a text document so that editors gives you the right writing environment for plain text.

==== Macros (Newcommands), Cross-References, Index, and Bibliography ===== label{newcommands}

Doconce supports a type of macros via a LaTeX-style *newcommand* construction. The newcommands defined in a file with name 'newcommand_replace.tex' are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names 'newcommands.tex' and 'newcommands_keep.tex' are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by '!bt' and '!et' in 'newcommands_keep.tex' to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in 'newcommands_replace.tex' and expanded by Doconce. The definitions of newcommands in the 'newcommands*.tex' files *must* appear on a single

,,

line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the 'doc/manual/manual.do.txt' file (see the "demo page": "https://doconce.googlecode.com/hg/doc/demos/manual/index.html" for various formats of this document).

- # Example on including another Doconce file (using preprocess):
- # #include "_doconce2anything.do.txt"

==== Demos =====

The current text is generated from a Doconce format stored in the file !bc

docs/tutorial/tutorial.do.txt

!ec

The file 'make.sh' in the 'tutorial' directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, 'tutorial.do.txt' is the starting point. Running 'make.sh' and studying the various generated files and comparing them with the original 'tutorial.do.txt' file, gives a quick introduction to how Doconce is used in a real case. "Here": "https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html" is a sample of how this tutorial looks in different formats.

There is another demo in the 'docs/manual' directory which translates the more comprehensive documentation, 'manual.do.txt', to various formats. The 'make.sh' script runs a set of translations.

#include "../manual/install.do.txt"

Doconce: Document Once, Include Anywhere

Hans Petter Langtangen^{1,2}

¹Simula Research Laboratory ²University of Oslo

Dec 26, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LATEX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

1 The Doconce Concept

Doconce is two things:

1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LATEX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2* programs) go to XML, HTML, LATEX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LATEX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.

2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than Lagrange and HTML.
- Doconce can be converted to plain *untagged* text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code directly from the source code files via regular expressions for the start and end lines.
- Doconce has full support for LaTEX math and integrates well with big LaTEX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LATEX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- Contrary to the similar (and superior) Pandoc translator, Doconce supports Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- Large books written in LaTEX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants
 to appear as plain untagged text for viewing in Pydoc, as reStructuredText
 for use with Sphinx, as wiki text when publishing the software at web sites,
 and as LATEX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount
 of Doconce tagging is added, before the memos can appear as Sphinx
 web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LATEX, Sphinx, and similar formats.

2 What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing bc! (begin code) and ec! (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing bt! (begin TeX) and et! (end TeX) commands at separate lines before and after the math block.
- There is support for both LATEX and text-like inline mathematics.

- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
===== A Subsection with Sample Text =====
label{my:first:sec}
```

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item $\bar{3}$

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2 o item 3

URLs with a link word are possible, as in "hpl":"http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments of the form [name: comment] (with a space after 'name:'), e.g., such as [hpl: here I will make some remarks to the text]. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an

Tables are also supperted, e.g.,

	velocity	acceleration
0.0	1.4186 1.376512 1.1E+1	-5.01 11.919 14.717624

lines beginning with # are comment lines

The Doconce text above results in the following little document:

2.1 A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an o (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section 2.1.

Doconce also allows inline comments such as (**hpl**: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section 3 for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624

2.2 Mathematics and Computer Code

Inline mathematics, such as $\nu=\sin(x)$, allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like $\nu=\sin(x)$ is typeset as

```
\ln = \sin(x) \le \sin(x)
```

The pipe symbol acts as a delimiter between LATEX code and the plain text version of the formula. If you write a lot of mathematics, only the output formats latex, pdflatex, html, sphinx, and pandoc are of interest and all these support inline LATEX mathematics so then you will naturally drop the pipe symbol and write just

```
nu = \sin(x)
```

However, if you want more textual formats, like plain text or reStructuredText, the text after the pipe symbol may help to make the math formula more readable if there are backslahes or other special LATEX symbols in the LATEX code.

Blocks of mathematics are better typeset with raw LATEX, inside bt! and et! (begin tex / end tex) instructions. The result looks like this:

$$\frac{\partial u}{\partial t} = \nabla^2 u + f, \qquad (1)$$

$$\frac{\partial v}{\partial t} = \nabla \cdot (q(u)\nabla v) + g \qquad (2)$$

$$\frac{\partial v}{\partial t} = \nabla \cdot (q(u)\nabla v) + g \tag{2}$$

Of course, such blocks only looks nice in formats with support for LATEX mathematics, and here the align environment in particular (this includes latex, pdflatex, html, and sphinx). The raw LATEX syntax appears in simpler formats, but can still be useful for those who can read LaTEX syntax.

You can have blocks of computer code, starting and ending with bc! and ec! instructions, respectively. Such blocks are formatted as

```
from math import sin, pi
def myfunc(x):
   return sin(pi*x)
import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., bc xxx! where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LATEX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with bc pro!, while a part of a file is copied into a bc cod! environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LATEX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

2.3 Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style <code>newcommand</code> construction. The newcommands defined in a file with name <code>newcommand_replace.tex</code> are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names <code>newcommands.tex</code> and <code>newcommands_keep.tex</code> are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by bt! and et! in <code>newcommands_keep.tex</code> to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in <code>newcommands_replace.tex</code> and expanded by Doconce. The definitions of newcommands in the <code>newcommands*.tex</code> files <code>must</code> appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the Latextary and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of Latextary making it easy for Doconce documents to be integrated in Latextary projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

3 From Doconce to Other Formats

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

or just

Terminal> doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example,

```
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5  # preprocess
Terminal> doconce format latex yourdoc extra_sections=True VAR1=5  # mako
```

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

The command-line arguments --no-preprocess and --no-make turn off running preprocess and make, respectively.

Inline comments in the text are removed from the output by

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal> doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

3.1 HTML

Making an HTML version of a Doconce file mydoc.do.txt is performed by

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing. The HTML style is defined in the header of the file. The default style has blue section headings and white background. With the --html-solarized command line argument, the solarized color palette is used.

If the Pygments package (including the pygmentize program) is installed, code blocks are typeset with aid of this package. The command-line argument --no-pygments-html turns off the use of Pygments and makes code blocks appear with plain (pre) HTML tags. The option --pygments-html-linenos turns on line numbers in Pygments-formatted code blocks.

The HTML file can be embedded in a template if the Doconce document does not have a title (because then there will be no header and footer in the HTML file). The template file must contain valid HTML code and can have three "slots": %(title)s for a title, %(date)s for a date, and %(main)s for the main body of text, i.e., the Doconce document translated to HTML. The title becomes the first heading in the Doconce document, and the date is extracted from the DATE: line, if present. With the template feature one can easily embed the text in the look and feel of a website. The template can be extracted from the source code of a page at the site; just insert %(title)s and %(date)s at appropriate places and replace the main bod of text by %(main)s. Here is an example:

Terminal> doconce format html mydoc --html-template=mytemplate.html

3.2 Pandoc and Markdown

Output in Pandoc's extended Markdown format results from

Terminal> doconce format pandoc mydoc

The name of the output file is mydoc.mkd. From this format one can go to numerous other formats:

Terminal> pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or Latex to the output format instead of ignoring it, while the --toc option generates a table of contents. See the Pandoc documentation for the many features of the pandoc program.

Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word. There are two ways (experiment to find the best one for your document): doconce format pandoc and then translating using pandoc, or doconce format latex, and then going from LaTeX to the desired format using pandoc. Here is an example on the latter strategy:

Terminal> doconce format latex mydoc
Terminal> doconce ptex2tex mydoc
Terminal> pandoc -f latex -t docx -o mydoc.docx mydoc.tex

When we go through pandoc, only single equations or align* environments are well understood.

Quite some doconce replace and doconce subst edits might be needed on the .mkd or .tex files to successfully have mathematics that is well translated to MS Word. Also when going to reStructuredText using Pandoc, it can be advantageous to go via LATEX.

Here is an example where we take a Doconce snippet (without title, author, and date), maybe with some unnumbered equations, and quickly generate HTML with mathematics displayed my MathJax:

```
Terminal> doconce format pandoc mydoc
Terminal> pandoc -t html -o mydoc.html -s --mathjax mydoc.mkd
```

The -s option adds a proper header and footer to the mydoc.html file. This recipe is a quick way of makeing HTML notes with (some) mathematics.

3.3 LATEX

Making a LATEX file mydoc.tex from mydoc.do.txt is done in two steps:

Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for the ptex2tex program (or doconce ptex2tex):

```
Terminal> doconce format latex mydoc
```

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands_keep.tex, or newcommands_replace.tex (see Section 2.3). If these files are present, they are included in the LATEX document so that your commands are defined.

An option --latex-printed makes some adjustments for documents aimed at being printed. For example, links to web resources are associated with a footnote listing the complete web address (URL).

Step 2. Run ptex2tex (if you have it) to make a standard LATEX file,

Terminal
erminal> ptex2tex mydoc
case you do not have ptex2tex, you may run a (very) simplified version:
erminal> doconce ptex2tex mydoc

Note that Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTEX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run

```
Terminal> ptex2tex -DHELVETICA mydoc
Terminal> doconce ptex2tex mydoc -DHELVETICA # alternative
```

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LATEX "maketitle" heading is also available through -DLATEX_HEADING=traditional. A separate titlepage can be generate by -DLATEX_HEADING=titlepage.

Preprocessor variables to be defined or undefined are

- BOOK for the "book" documentclass rather than the standard "article" class (necessary if you apply chapter headings)
- PALATINO for the Palatino font
- HELVETIA for the Helvetica font
- A4PAPER for A4 paper size
- A6PAPER for A6 paper size (suitable for reading on small devices)
- MOVIE15 for using the movie15 LATEX package to display movies
- PREAMBLE to turn the LATEX preamble on or off (i.e., complete document or document to be included elsewhere)
- MINTED for inclusion of the minted package (which requires latex or pdflatex to be run with the -shell-escape option)

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any bc! command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., bc sys! for a terminal session, where sys is set to a certain environment in .ptex2tex.cfg (e.g., CodeTerminal). There are about 40 styles to choose from, and you can easily add new ones.

Also the doconce ptex2tex command supports preprocessor directives for processing the .p.tex file. The command allows specifications of code environments as well. Here is an example:

```
Terminal doconce ptex2tex mydoc -DLATEX_HEADING=traditional \
-DPALATINO -DA6PAPER \
"sys=\begin{quote}\begin{verbatim}@\end{verbatim}\end{quote}" \
fpro=minted fcod=minted shcod=Verbatim envir=ans:nt
```

Note that @ must be used to separate the begin and end LTEX commands, unless only the environment name is given (such as minted above, which implies \begin{minted}{fortran} and \end{minted} as begin and end for blocks inside bc fpro! and ec!). Specifying envir=ans:nt means that all other environments are typeset with the anslistings.sty package, e.g., bc cppcod! will then result in \begin{c++}. If no environments like sys, fpro, or the common envir are defined on the command line, the plain \begin{verbatim} and \end{verbatim} used.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples:

```
Terminal> doconce replace 'section{' 'section*{' mydoc.tex}
Terminal> doconce subst 'title\{(.+)Using (.+)\}' \
    'title{\g<1> \\\ [1.5mm] Using \g<2>' mydoc.tex
```

A lot of tailored fixes to the LATEX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LATEX file.

Step 3. Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to run ptex2tex and use the minted LaTeX package for type-setting code blocks (Minted_Python, Minted_Cpp, etc., in ptex2tex specified through the *pro and *cod variables in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LaTeX package is needed. This package is included by running ptex2tex with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

When running doconce ptex2tex mydoc envir=minted (or other minted specifications with doconce ptex2tex), the minted package is automatically included so there is no need for the -DMINTED option.

3.4 PDFLaTeX

Running pdflatex instead of latex follows almost the same steps, but the start is

```
Terminal> doconce format latex mydoc

Then ptex2tex is run as explained above, and finally

Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> pdflatex -shell-escape mydoc
```

3.5 Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

3.6 reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal> doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html
- http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

3.7 Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx_dir command:

```
Terminal> doconce sphinx_dir author="authors' names" \
    title="some title" version=1.0 dirname=sphinxdir \
    theme=mytheme file1 file2 file3 ...
```

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs

Terminal> doconce sphinx_dir mydoc

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx_dir command generates a script automake_sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake_sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

The doconce sphinx_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake_sphinx.py must be edited accordingly. Files, to which there are local links (not http: or file: URLs), must be placed in the _static subdirectory of the Sphinx directory. The utility doconce sphinxfix_localURLs is run to check for local links in the Doconce file: for each such link, say dir1/dir2/myfile.txt it replaces the link by _static/myfile.txt and copies dir1/dir2/myfile.txt to a local _static directory (in the same directory as the script is run). However, we recommend instead that the writer of the document places files in _static or lets a script do it automatically. The user must copy all _static/* files to the _static subdirectory of the Sphinx directory. It may be wise to always put files, to which there are local links in the Doconce document, in a _static or _static-name directory and use these local links. Then links do not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the <code>conf.py</code> configuration file for Sphinx is edited accordingly, and a script <code>make-themes.sh</code> can make HTML documents with one or more themes. For example, to realize the themes <code>fenics</code> and <code>pyramid</code>, one writes

Terminal> ./make-themes.sh fenics pyramid

The resulting directories with HTML documents are _build/html_fenics and _build/html_pyramid, respectively. Without arguments, make-themes.sh makes

all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format:

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
Terminal
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
Name of My Sphinx Document
Author
version
version
.rst
index
у
n
n
n
n
n
у
ĚOF
```

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

Step 3. Copy the mydoc.rst file to the Sphinx root directory:

Terminal> cp mydoc.rst sphinx-rootdir

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the _static directory, see comment above.

Step 4. Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes

```
.. toctree::
    :maxdepth: 2
    mydoc
```

(The spaces before mydoc are important!)

Step 5. Generate, for instance, an HTML version of the Sphinx source:

```
make clean # remove old versions
make html
```

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LTEX, PDF (via LTEX), pure text, man pages, and Texinfo files.

Step 6. View the result:

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows bc!: cod gives Python (code-block:: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

3.8 Wiki Formats

There are many different wiki formats, but Doconce only supports three: Googlecode wiki, MediaWiki, and Creole Wiki. These formats are called gwiki, mwiki, and cwiki, respectively. Transformation from Doconce to these formats is done by

```
Terminal> doconce format gwiki mydoc.do.txt
Terminal> doconce format mwiki mydoc.do.txt
Terminal> doconce format cwiki mydoc.do.txt
```

The Googlecode wiki document, mydoc.gwiki, is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.

When the Doconce file contains figures, each figure filename must in the .gwiki file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

From the MediaWiki format one can go to other formats with aid of mwlib. This means that one can easily use Doconce to write Wikibooks and publish these in PDF and MediaWiki format. At the same time, the book can also be published as a standard LATEX book or a Sphinx web document.

3.9 Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to re-StructuredText. Since Doconce does not know if the <code>.rst</code> file is going to be filtered to LATEX or HTML, it cannot know if <code>.eps</code> or <code>.png</code> is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The <code>make.sh</code> files in <code>docs/manual</code> and <code>docs/tutorial</code> constitute comprehensive examples on how such scripts can be made.

3.10 Demos

The current text is generated from a Doconce format stored in the file

docs/tutorial/tutorial.do.txt

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

4 Installation of Doconce and its Dependencies

4.1 Doconce

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hg) source follows the standard procedure:

```
____ Terminal ___
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
sudo python setup.py install
cd ..
Since Doconce is frequently updated, it is recommended to use the above
procedure and whenever a problem occurs, make sure to update to the most
recent version:
cd doconce
hg pull
hg update
sudo python setup.py install
   Debian GNU/Linux users can also run
                                 __ Terminal
sudo apt-get install doconce
This installs the latest release and not the most updated and bugfixed version.
On Ubuntu one needs to run
                        _____Terminal _
\verb+sudo+ add-apt-repository+ ppa:scitools/ppa+\\
sudo apt-get update
sudo apt-get install doconce
```

4.2 Dependencies

Preprocessors. If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess cd preprocess cd doconce sudo python setup.py install cd ..
```

pip install Mako

This command requires pip to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by

Alternatively, one can install from the pip source code.

sudo apt-get install python-pip

Make can also be installed directly from source: download the tarball, pack it out, go to the directory and run the usual sudo python setup.py install.

Ptex2tex for LaTeX Output. To make LaTeX documents with very flexible choice of typesetting of verbatim code blocks you need ptex2tex, which is installed by

```
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex cd ptex2tex sudo python setup.py install
```

It may happen that you need additional style files, you can run a script, cp2texmf.sh:

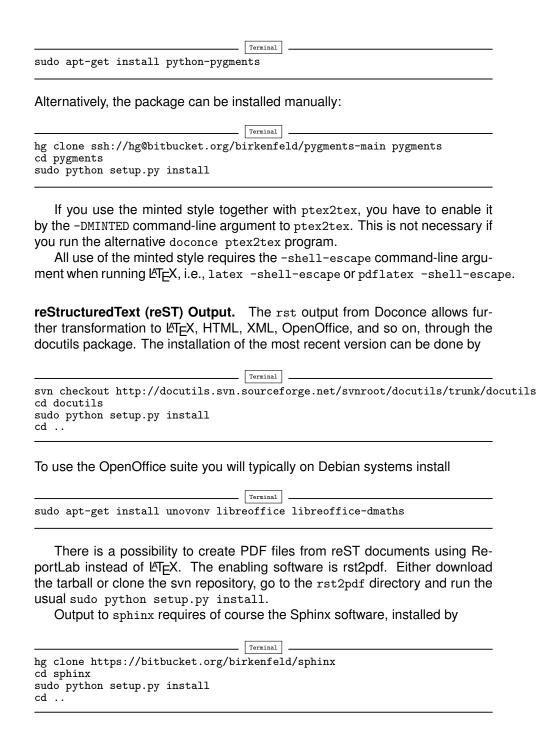

```
cd latex sh cp2texmf.sh # copy stylefiles to ~/texmf directory cd ../..
```

This script copies some special stylefiles that that ptex2tex potentially makes use of. Some more standard stylefiles are also needed. These are installed by

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the $^{\sim}/\text{texmf/tex/latex/misc}$ directory).

Note that the doconce ptex2tex command, which needs no installation beyond Doconce itself, can be used as a simpler alternative to the ptex2tex program.

The *minted* LaTeX style is offered by ptex2tex and doconce ptext2tex is popular among many users. This style requires the package Pygments to be installed. On Debian Linux,

Markdown and Pandoc Output. The Doconce format pandoc outputs the document in the Pandoc extended Markdown format, which via the pandoc program can be translated to a range of other formats. Installation of Pandoc, written in Haskell, is most easily done by

sudo apt-get inst	all pandoc	Terminal] ———
Epydoc Output. too, installed by	When the output	forma	at is epydoc one needs that program
svn co https://ep cd epydoc sudo make install cd	•	Terminal orge.ne]

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install.

Doconce: Document Once, Include Anywhere

Author: Hans Petter Langtangen

Date: Dec 26, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki?
 Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

The Doconce Concept

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain *untagged* text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code directly from the source code files via regular expressions for the start and end lines.
- Doconce has full support for LaTeX math and integrates well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- Contrary to the similar (and superior) Pandoc translator, Doconce supports Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as re-StructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
===== A Subsection with Sample Text =====
label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look
```

natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments of the form [name: comment] (with a space after 'name:'), e.g., such as [hpl: here I will make some remarks to the text]. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r-	 r	
0.0	1.4186	-5.01
1 2.0	1.376512	11.919
4.0	1.1E+1	14.717624

lines beginning with # are comment lines

The Doconce text above results in the following little document:

A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an \circ (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section A Subsection with Sample Text.

Doconce also allows inline comments such as (**hpl**: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section From Doconce to Other Formats for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624

Mathematics and Computer Code

Inline mathematics, such as $v = \sin(x)$, allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like $v = \sin(x)$ is typeset as:

```
\alpha = \sin(x) = \sin(x)
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula. If you write a lot of mathematics, only the output formats latex, pdflatex, html, sphinx, and pandoc are of interest and all these support inline LaTeX mathematics so then you will naturally drop the pipe symbol and write just:

```
\ln = \sin(x)
```

However, if you want more textual formats, like plain text or reStructuredText, the text after the pipe symbol may help to make the math formula more readable if there are backslahes or other special LaTeX symbols in the LaTeX code.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions. The result looks like this:

```
\begin{align} {\partial u vover partial t} &= \nabla^2 u + f, label{myeq1} \\ {\partial v vover partial t} &= \nabla cdot(q(u) \nabla v) + g \\ end{align}
```

Of course, such blocks only looks nice in formats with support for LaTeX mathematics, and here the align environment in particular (this includes latex, pdflatex, html, and sphinx). The raw LaTeX syntax appears in simpler formats, but can still be useful for those who can read LaTeX syntax.

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks are formatted as:

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

```
# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
```

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style <code>newcommand</code> construction. The newcommands defined in a file with name <code>newcommand_replace.tex</code> are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names <code>newcommands.tex</code> and <code>newcommands_keep.tex</code> are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand

all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by !bt and !et in newcommands_keep.tex to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in newcommands_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands*.tex files must appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

From Doconce to Other Formats

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

```
Terminal> doconce format format mydoc.do.txt
or just:
```

Terminal> doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example:

```
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5  # preprotection  # preprotection  # preprotection  # preprotection  # make  #
```

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

The command-line arguments —no-preprocess and —no-make turn off running preprocess and make, respectively.

Inline comments in the text are removed from the output by:

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal > doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

HTML

Making an HTML version of a Doconce file mydoc.do.txt is performed by:

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing. The HTML style is defined in the header of the file. The default style has blue section headings and white background. With the --html-solarized command line argument, the solarized color palette is used.

If the Pygments package (including the pygmentize program) is installed, code blocks are typeset with aid of this package. The command-line argument --no-pygments-html turns off the use of Pygments and makes code blocks appear with plain (pre) HTML tags. The option --pygments-html-linenos turns on line numbers in Pygments-formatted code blocks.

The HTML file can be embedded in a template if the Doconce document does not have a title (because then there will be no header and footer in the HTML file). The template file must contain valid HTML code and can have three "slots": %(title)s for a title, %(date)s for a date, and %(main)s for the main body of text, i.e., the Doconce document translated to HTML. The title becomes the first heading in the Doconce document, and the date is extracted from the DATE: line, if present. With the template feature one can easily embed the text in the look and feel of a website. The template can be extracted from the source code of a page at the site; just insert %(title)s and %(date)s at appropriate places and replace the main bod of text by %(main)s. Here is an example:

Terminal> doconce format html mydoc --html-template=mytemplate.html

Pandoc and Markdown

Output in Pandoc's extended Markdown format results from:

```
Terminal> doconce format pandoc mydoc
```

The name of the output file is mydoc.mkd. From this format one can go to numerous other formats:

```
Terminal> pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd
```

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it, while the --toc option generates a table of contents. See the Pandoc documentation for the many features of the pandoc program.

Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word. There are two ways (experiment to find the best one for your document): doconce format pandoc and then translating using pandoc, or doconce format latex, and then going from LaTeX to the desired format using pandoc. Here is an example on the latter strategy:

```
Terminal> doconce format latex mydoc
Terminal> doconce ptex2tex mydoc
Terminal> pandoc -f latex -t docx -o mydoc.docx mydoc.tex
```

When we go through pandoc, only single equations or $align \star environments$ are well understood.

Quite some doconce replace and doconce subst edits might be needed on the .mkd or .tex files to successfully have mathematics that is well translated to MS Word. Also when going to reStructuredText using Pandoc, it can be advantageous to go via LaTeX.

Here is an example where we take a Doconce snippet (without title, author, and date), maybe with some unnumbered equations, and quickly generate HTML with mathematics displayed my MathJax:

```
Terminal> doconce format pandoc mydoc
Terminal> pandoc -t html -o mydoc.html -s --mathjax mydoc.mkd
```

The -s option adds a proper header and footer to the mydoc.html file. This recipe is a quick way of makeing HTML notes with (some) mathematics.

LaTeX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps: .. Note: putting code blocks inside a list is not successful in many

Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for the ptex2tex program (or doconce ptex2tex):

```
Terminal> doconce format latex mydoc
```

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands_keep.tex, or newcommands_replace.tex (see the section Macros (Newcommands), Cross-References, Index, and Bibliography). If these files are present, they are included in the LaTeX document so that your commands are defined.

An option --latex-printed makes some adjustments for documents aimed at being printed. For example, links to web resources are associated with a footnote listing the complete web address (URL).

Step 2. Run ptex2tex (if you have it) to make a standard LaTeX file:

```
Terminal> ptex2tex mydoc
```

In case you do not have ptex2tex, you may run a (very) simplified version:

```
Terminal> doconce ptex2tex mydoc
```

Note that Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run:

```
Terminal> ptex2tex -DHELVETICA mydoc
Terminal> doconce ptex2tex mydoc -DHELVETICA # alternative
```

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through <code>-DLATEX_HEADING=traditional</code>. A separate titlepage can be generate by <code>-DLATEX_HEADING=titlepage</code>.

Preprocessor variables to be defined or undefined are

- BOOK for the "book" documentclass rather than the standard "article" class (necessary if you apply chapter headings)
- PALATINO for the Palatino font
- HELVETIA for the Helvetica font
- A4PAPER for A4 paper size
- A6PAPER for A6 paper size (suitable for reading on small devices)
- MOVIE15 for using the movie15 LaTeX package to display movies
- PREAMBLE to turn the LaTeX preamble on or off (i.e., complete document or document to be included elsewhere)
- MINTED for inclusion of the minted package (which requires latex or pdflatex to be run with the -shell-escape option)

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc sys for a terminal session, where sys is set to a certain environment in .ptex2tex.cfg (e.g., CodeTerminal). There are about 40 styles to choose from, and you can easily add new ones.

Also the doconce ptex2tex command supports preprocessor directives for processing the .p.tex file. The command allows specifications of code environments as well. Here is an example:

Note that @ must be used to separate the begin and end LaTeX commands, unless only the environment name is given (such as minted above, which implies \begin {minted} {fortran} and \end{minted} as begin and end for blocks inside !bc fpro and !ec). Specifying envir=ans:nt means that all other environments are typeset with the anslistings.sty package, e.g., !bc cppcod will then result in \begin{c++}. If no environments like sys, fpro, or the common envir are defined on the command line, the plain \begin{verbatim} and \end{verbatim} used.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples:

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

Step 3. Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to run ptex2tex and use the minted LaTeX package for typesetting code blocks (Minted_Python, Minted_Cpp, etc., in ptex2tex specified through the *pro and *cod variables in .ptex2tex.cfg or θ 0 \$HOME/.ptex2tex.cfg, the minted LaTeX package is needed. This package is included by running ptex2tex with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

When running doconce ptex2tex mydoc envir=minted (or other minted specifications with doconce ptex2tex), the minted package is automatically included so there is no need for the -DMINTED option.

PDFLaTeX

Running pdflatex instead of latex follows almost the same steps, but the start is:

```
Terminal> doconce format latex mydoc
```

Then ptex2tex is run as explained above, and finally:

```
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> pdflatex -shell-escape mydoc
```

Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal> doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run:

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html
- http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx_dir command:

```
Terminal> doconce sphinx_dir author="authors' names" \
    title="some title" version=1.0 dirname=sphinxdir \
    theme=mytheme file1 file2 file3 ...
```

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs:

```
Terminal> doconce sphinx_dir mydoc
```

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx_dir command generates a script automake_sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake_sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

The doconce sphinx_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake_sphinx.py must be edited accordingly. Files, to which there are local links (not http: or file: URLs), must be placed in the _static subdirectory of the Sphinx directory. The utility doconce sphinxfix_localURLs is run to check for local links in the Doconce file: for each such link, say dir1/dir2/myfile.txt it replaces the link by_static/myfile.txt and copies dir1/dir2/myfile.txt to a local_static directory (in the same directory as the script is run). However, we recommend instead that the writer of the document places files in_static or lets a script do it automatically. The user must copy all _static/* files to the _static subdirectory of the Sphinx directory. It may be wise to always put files, to which there are local links in the Doconce document, in a _static or _static-name directory and use these local links. Then links do not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the <code>conf.py</code> configuration file for Sphinx is edited accordingly, and a script <code>make-themes.sh</code> can make HTML documents with one or more themes. For example, to realize the themes <code>fenics</code> and <code>pyramid</code>, one writes:

```
Terminal> ./make-themes.sh fenics pyramid
```

The resulting directories with HTML documents are _build/html_fenics and _build/html_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format:

```
Terminal> doconce format sphinx mydoc
```

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
n
-
Name of My Sphinx Document
Author
version
version</pre>
```

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

Step 3. Copy the mydoc.rst file to the Sphinx root directory:

```
Terminal> cp mydoc.rst sphinx-rootdir
```

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the _static directory, see comment above.

Step 4. Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes:

```
.. toctree::
    :maxdepth: 2

mydoc
```

(The spaces before mydoc are important!)

Step 5. Generate, for instance, an HTML version of the Sphinx source:

```
make clean  # remove old versions
make html
```

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

Step 6. View the result:

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows !bc: cod gives Python (code-block: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

Wiki Formats

There are many different wiki formats, but Doconce only supports three: Googlecode wiki, MediaWiki, and Creole Wiki. These formats are called gwiki, mwiki, and cwiki, respectively. Transformation from Doconce to these formats is done by:

```
Terminal> doconce format gwiki mydoc.do.txt
Terminal> doconce format mwiki mydoc.do.txt
Terminal> doconce format cwiki mydoc.do.txt
```

The Googlecode wiki document, mydoc.gwiki, is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.

When the Doconce file contains figures, each figure filename must in the .gwiki file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

From the MediaWiki format one can go to other formats with aid of mwlib. This means that one can easily use Doconce to write Wikibooks and publish these in PDF and MediaWiki format. At the same time, the book can also be published as a standard LaTeX book or a Sphinx web document.

Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

Demos

The current text is generated from a Doconce format stored in the file:

```
docs/tutorial/tutorial.do.txt
```

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

Installation of Doconce and its Dependencies

Doconce

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hg) source follows the standard procedure:

```
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
```

Since Doconce is frequently updated, it is recommended to use the above procedure and whenever a problem occurs, make sure to update to the most recent version:

```
cd doconce
hg pull
hg update
sudo python setup.py install
```

Debian GNU/Linux users can also run:

```
sudo apt-get install doconce
```

This installs the latest release and not the most updated and bugfixed version. On Ubuntu one needs to run:

```
sudo add-apt-repository ppa:scitools/ppa
sudo apt-get update
sudo apt-get install doconce
```

Dependencies

Preprocessors

If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
cd ..
```

A much more advanced alternative to Preprocess is Mako. Its installation is most conveniently done by pip:

```
pip install Mako
```

This command requires pip to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by:

```
sudo apt-get install python-pip
```

Alternatively, one can install from the pip source code.

Make can also be installed directly from source: download the tarball, pack it out, go to the directory and run the usual sudo python setup.py install.

Ptex2tex for LaTeX Output

To make LaTeX documents with very flexible choice of typesetting of verbatim code blocks you need ptex2tex, which is installed by:

```
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
```

It may happen that you need additional style files, you can run a script, cp2texmf.sh:

```
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
```

This script copies some special stylefiles that that ptex2tex potentially makes use of. Some more standard stylefiles are also needed. These are installed by:

```
sudo apt-get install texlive-latex-recommended texlive-latex-extra
```

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the ~/texmf/tex/latex/misc directory).

Note that the doconce ptex2tex command, which needs no installation beyond Doconce itself, can be used as a simpler alternative to the ptex2tex program.

The *minted* LaTeX style is offered by ptex2tex and doconce ptext2tex is popular among many users. This style requires the package Pygments to be installed. On Debian Linux:

```
sudo apt-get install python-pygments
```

Alternatively, the package can be installed manually:

```
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
```

If you use the minted style together with ptex2tex, you have to enable it by the -DMINTED command-line argument to ptex2tex. This is not necessary if you run the alternative doconce ptex2tex program.

All use of the minted style requires the -shell-escape command-line argument when running LaTeX, i.e., latex -shell-escape or pdflatex -shell-escape.

reStructuredText (reST) Output

The rst output from Doconce allows further transformation to LaTeX, HTML, XML, OpenOffice, and so on, through the docutils package. The installation of the most recent version can be done by:

```
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/doc
cd docutils
sudo python setup.py install
cd ..
```

To use the OpenOffice suite you will typically on Debian systems install:

```
sudo apt-get install unovonv libreoffice libreoffice-dmaths
```

There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is rst2pdf. Either download the tarball or clone the svn repository, go to the rst2pdf directory and run the usual sudo python setup.py install.

Output to sphinx requires of course the Sphinx software, installed by:

```
hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
cd ..
```

Markdown and Pandoc Output

The Doconce format pandoc outputs the document in the Pandoc extended Markdown format, which via the pandoc program can be translated to a range of other formats. Installation of Pandoc, written in Haskell, is most easily done by:

```
sudo apt-get install pandoc
```

Epydoc Output

When the output format is epydoc one needs that program too, installed by:

```
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ..
```

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install.

Date Dec 26, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

THE DOCONCE CONCEPT

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain untagged text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code directly from the source code files via regular expressions for the start and end lines.
- Doconce has full support for LaTeX math and integrates well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated
 markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make
 the initial versions of a Sphinx or wiki document.
- Contrary to the similar (and superior) Pandoc translator, Doconce supports Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.

• Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

WHAT DOES DOCONCE LOOK LIKE?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
==== A Subsection with Sample Text =====
label{my:first:sec}
```

```
Ordinary text looks like ordinary text, and the tags used for
_boldface_ words, *emphasized* words, and 'computer' words look
natural in plain text. Lists are typeset as you would do in an email,
  * item 1
  * item 2
  * item 3
Lists can also have automatically numbered items instead of bullets,
 o item 1
 o item 2
 o item 3
URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl".
If the word is URL, the URL itself becomes the link name,
as in "URL": "tutorial.do.txt".
References to sections may use logical names as labels (e.g., a
"label" command right after the section title), as in the reference to
Section ref{my:first:sec}.
Doconce also allows inline comments of the form [name: comment] (with
a space after 'name:'), e.g., such as [hpl: here I will make some
remarks to the text]. Inline comments can be removed from the output
by a command-line argument (see Section ref{doconce2formats} for an
example).
Tables are also supperted, e.g.,
  |time | velocity | acceleration |
  |---r----r------------------------|
  | 0.0 | 1.4186 | -5.01
  | 2.0 | 1.376512 | 11.919
```

lines beginning with # are comment lines

| 4.0 | 1.1E+1 | 14.717624

The Doconce text above results in the following little document:

3.1 A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an o (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2

3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section A Subsection with Sample Text.

Doconce also allows inline comments such as (**hpl**: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section *From Doconce to Other Formats* for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration	
0.0	1.4186	-5.01	
2.0	1.376512	11.919	
4.0	1.1E+1	14.717624	

3.2 Mathematics and Computer Code

Inline mathematics, such as $\nu = \sin(x)$, allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like $\nu = \sin(x)$ is typeset as

```
\alpha = \sin(x) = \sin(x)
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula. If you write a lot of mathematics, only the output formats latex, pdflatex, html, sphinx, and pandoc are of interest and all these support inline LaTeX mathematics so then you will naturally drop the pipe symbol and write just

```
\alpha = \sin(x)
```

However, if you want more textual formats, like plain text or reStructuredText, the text after the pipe symbol may help to make the math formula more readable if there are backslahes or other special LaTeX symbols in the LaTeX code.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions. The result looks like this:

$$\begin{split} \frac{\partial u}{\partial t} &= \nabla^2 u + f, \\ \frac{\partial v}{\partial t} &= \nabla \cdot (q(u)\nabla v) + g \end{split} \tag{3.1}$$

Of course, such blocks only looks nice in formats with support for LaTeX mathematics, and here the align environment in particular (this includes latex, pdflatex, html, and sphinx). The raw LaTeX syntax appears in simpler formats, but can still be useful for those who can read LaTeX syntax.

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks are formatted as

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

```
# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
```

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

3.3 Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style newcommand construction. The newcommands defined in a file with name newcommand_replace.tex are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names newcommands.tex and newcommands_keep.tex are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by !bt and !et in newcommands_keep.tex to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in newcommands_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands*.tex files must appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

FROM DOCONCE TO OTHER FORMATS

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

Terminal> doconce format format mydoc.do.txt

or just

Terminal> doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example,

```
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5  # preprocess
Terminal> doconce format latex yourdoc extra_sections=True VAR1=5  # mako
```

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

The command-line arguments —no-preprocess and —no-make turn off running preprocess and make, respectively.

Inline comments in the text are removed from the output by

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal> doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

4.1 HTML

Making an HTML version of a Doconce file mydoc.do.txt is performed by

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing.

The HTML style is defined in the header of the file. The default style has blue section headings and white background. With the --html-solarized command line argument, the solarized color palette is used.

If the Pygments package (including the pygmentize program) is installed, code blocks are typeset with aid of this package. The command-line argument --no-pygments-html turns off the use of Pygments and makes code blocks appear with plain (pre) HTML tags. The option --pygments-html-linenos turns on line numbers in Pygments-formatted code blocks.

The HTML file can be embedded in a template if the Doconce document does not have a title (because then there will be no header and footer in the HTML file). The template file must contain valid HTML code and can have three "slots": % (title) s for a title, % (date) s for a date, and % (main) s for the main body of text, i.e., the Doconce document translated to HTML. The title becomes the first heading in the Doconce document, and the date is extracted from the DATE: line, if present. With the template feature one can easily embed the text in the look and feel of a website. The template can be extracted from the source code of a page at the site; just insert % (title) s and % (date) s at appropriate places and replace the main bod of text by % (main) s. Here is an example:

```
Terminal> doconce format html mydoc --html-template=mytemplate.html
```

4.2 Pandoc and Markdown

Output in Pandoc's extended Markdown format results from

```
Terminal> doconce format pandoc mydoc
```

The name of the output file is mydoc.mkd. From this format one can go to numerous other formats:

```
Terminal> pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd
```

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it, while the --toc option generates a table of contents. See the Pandoc documentation for the many features of the pandoc program.

Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word. There are two ways (experiment to find the best one for your document): doconce format pandoc and then translating using pandoc, or doconce format latex, and then going from LaTeX to the desired format using pandoc. Here is an example on the latter strategy:

```
Terminal> doconce format latex mydoc
Terminal> doconce ptex2tex mydoc
Terminal> pandoc -f latex -t docx -o mydoc.docx mydoc.tex
```

When we go through pandoc, only single equations or align* environments are well understood.

Quite some doconce replace and doconce subst edits might be needed on the .mkd or .tex files to successfully have mathematics that is well translated to MS Word. Also when going to reStructuredText using Pandoc, it can be advantageous to go via LaTeX.

Here is an example where we take a Doconce snippet (without title, author, and date), maybe with some unnumbered equations, and quickly generate HTML with mathematics displayed my MathJax:

```
Terminal> doconce format pandoc mydoc
Terminal> pandoc -t html -o mydoc.html -s --mathjax mydoc.mkd
```

The -s option adds a proper header and footer to the mydoc.html file. This recipe is a quick way of makeing HTML notes with (some) mathematics.

4.3 LaTeX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps: .. Note: putting code blocks inside a list is not successful in many

Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for the ptex2tex program (or doconce ptex2tex):

```
Terminal> doconce format latex mydoc
```

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands_keep.tex, or newcommands_replace.tex (see the section *Macros* (*Newcommands*), *Cross-References*, *Index*, *and Bibliography*). If these files are present, they are included in the LaTeX document so that your commands are defined.

An option ——latex—printed makes some adjustments for documents aimed at being printed. For example, links to web resources are associated with a footnote listing the complete web address (URL).

Step 2. Run ptex2tex (if you have it) to make a standard LaTeX file,

```
Terminal> ptex2tex mydoc
```

In case you do not have ptex2tex, you may run a (very) simplified version:

```
Terminal> doconce ptex2tex mydoc
```

Note that Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run

```
Terminal> ptex2tex -DHELVETICA mydoc
Terminal> doconce ptex2tex mydoc -DHELVETICA # alternative
```

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through <code>-DLATEX_HEADING=traditional</code>. A separate titlepage can be generate by <code>-DLATEX_HEADING=titlepage</code>.

Preprocessor variables to be defined or undefined are

- BOOK for the "book" documentclass rather than the standard "article" class (necessary if you apply chapter headings)
- PALATINO for the Palatino font
- HELVETIA for the Helvetica font
- A4PAPER for A4 paper size
- A6PAPER for A6 paper size (suitable for reading on small devices)
- MOVIE15 for using the movie15 LaTeX package to display movies
- PREAMBLE to turn the LaTeX preamble on or off (i.e., complete document or document to be included elsewhere)
- MINTED for inclusion of the minted package (which requires latex or pdflatex to be run with the -shell-escape option)

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc sys for a terminal session, where sys is set to a certain

4.3. LaTeX 13

environment in .ptex2tex.cfg (e.g., CodeTerminal). There are about 40 styles to choose from, and you can easily add new ones.

Also the doconce ptex2tex command supports preprocessor directives for processing the .p.tex file. The command allows specifications of code environments as well. Here is an example:

```
Terminal> doconce ptex2tex mydoc -DLATEX_HEADING=traditional \
    -DPALATINO -DA6PAPER \
    "sys=\begin{quote}\begin{verbatim}@\end{verbatim}\end{quote}" \
    fpro=minted fcod=minted shcod=Verbatim envir=ans:nt
```

Note that @ must be used to separate the begin and end LaTeX commands, unless only the environment name is given (such as minted above, which implies \begin{minted} {fortran} and \end{minted} as begin and end for blocks inside !bc fpro and !ec). Specifying envir=ans:nt means that all other environments are typeset with the anslistings.sty package, e.g., !bc cppcod will then result in \begin{c++}. If no environments like sys, fpro, or the common envir are defined on the command line, the plain \begin{verbatim} and \end{verbatim} used.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples:

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

Step 3. Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to run ptex2tex and use the minted LaTeX package for typesetting code blocks (Minted_Python, Minted_Cpp, etc., in ptex2tex specified through the *pro and *cod variables in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LaTeX package is needed. This package is included by running ptex2tex with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

When running doconce ptex2tex mydoc envir=minted (or other minted specifications with doconce ptex2tex), the minted package is automatically included so there is no need for the -DMINTED option.

4.4 PDFLaTeX

Running pdflatex instead of latex follows almost the same steps, but the start is

```
Terminal> doconce format latex mydoc
```

Then ptex2tex is run as explained above, and finally

```
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> pdflatex -shell-escape mydoc
```

4.5 Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

4.6 reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal> doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html

4.4. PDFLaTeX

• http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

4.7 Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx_dir command:

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs

```
Terminal> doconce sphinx_dir mydoc
```

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx_dir command generates a script automake_sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake_sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

The doconce sphinx_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake_sphinx.py must be edited accordingly. Files, to which there are local links (not http: or file: URLs), must be placed in the _static subdirectory of the Sphinx directory. The utility doconce sphinxfix_localURLs is run to check for local links in the Doconce file: for each such link, say dir1/dir2/myfile.txt it replaces the link by _static/myfile.txt and copies dir1/dir2/myfile.txt to a local _static directory (in the same directory as the script is run). However, we recommend instead that the writer of the document places files in _static or lets a script do it automatically. The user must copy all _static/* files to the _static subdirectory of the Sphinx directory. It may be wise to always put files, to which there are local links in the Doconce document, in a _static or _static-name directory and use these local links. Then links do not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the <code>conf.py</code> configuration file for Sphinx is edited accordingly, and a script <code>make-themes.sh</code> can make HTML documents with one or more themes. For example, to realize the themes <code>fenics</code> and <code>pyramid</code>, one writes

```
Terminal> ./make-themes.sh fenics pyramid
```

The resulting directories with HTML documents are _build/html_fenics and _build/html_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format:

Terminal> doconce format sphinx mydoc

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
Name of My Sphinx Document
Author
version
version
.rst
index
n
У
n
n
n
n
n
n
У
У
У
EOF
```

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

Step 3. Copy the mydoc.rst file to the Sphinx root directory:

```
Terminal> cp mydoc.rst sphinx-rootdir
```

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the _static directory, see comment above.

Step 4. Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes

```
.. toctree::
   :maxdepth: 2
   mydoc
```

(The spaces before mydoc are important!)

Step 5. Generate, for instance, an HTML version of the Sphinx source:

```
make clean # remove old versions
make html
```

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects),

4.7. Sphinx 17

epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

Step 6. View the result:

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows !bc: cod gives Python (code-block:: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

4.8 Wiki Formats

There are many different wiki formats, but Doconce only supports three: Googlecode wiki, MediaWiki, and Creole Wiki. These formats are called gwiki, mwiki, and cwiki, respectively. Transformation from Doconce to these formats is done by

```
Terminal> doconce format gwiki mydoc.do.txt
Terminal> doconce format mwiki mydoc.do.txt
Terminal> doconce format cwiki mydoc.do.txt
```

The Googlecode wiki document, mydoc.gwiki, is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.

When the Doconce file contains figures, each figure filename must in the .gwiki file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

From the MediaWiki format one can go to other formats with aid of mwlib. This means that one can easily use Doconce to write Wikibooks and publish these in PDF and MediaWiki format. At the same time, the book can also be published as a standard LaTeX book or a Sphinx web document.

4.9 Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

4.10 Demos

The current text is generated from a Doconce format stored in the file

```
docs/tutorial/tutorial.do.txt
```

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

4.10. Demos 19

CHAPTER

FIVE

INSTALLATION OF DOCONCE AND ITS DEPENDENCIES

5.1 Doconce

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hg) source follows the standard procedure:

```
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
```

Since Doconce is frequently updated, it is recommended to use the above procedure and whenever a problem occurs, make sure to update to the most recent version:

```
cd doconce
hg pull
hg update
sudo python setup.py install
```

Debian GNU/Linux users can also run

```
sudo apt-get install doconce
```

This installs the latest release and not the most updated and bugfixed version. On Ubuntu one needs to run

```
sudo add-apt-repository ppa:scitools/ppa
sudo apt-get update
sudo apt-get install doconce
```

5.2 Dependencies

5.2.1 Preprocessors

If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
```

```
sudo python setup.py install \operatorname{cd} ..
```

A much more advanced alternative to Preprocess is Mako. Its installation is most conveniently done by pip,

```
pip install Mako
```

This command requires pip to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by

```
sudo apt-get install python-pip
```

Alternatively, one can install from the pip source code.

Mako can also be installed directly from source: download the tarball, pack it out, go to the directory and run the usual sudo python setup.py install.

5.2.2 Ptex2tex for LaTeX Output

To make LaTeX documents with very flexible choice of typesetting of verbatim code blocks you need ptex2tex, which is installed by

```
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
```

It may happen that you need additional style files, you can run a script, cp2texmf.sh:

```
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
```

This script copies some special stylefiles that that ptex2tex potentially makes use of. Some more standard stylefiles are also needed. These are installed by

```
sudo apt-get install texlive-latex-recommended texlive-latex-extra
```

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the ~/texmf/tex/latex/misc directory).

Note that the doconce ptex2tex command, which needs no installation beyond Doconce itself, can be used as a simpler alternative to the ptex2tex program.

The minted LaTeX style is offered by ptex2tex and doconce ptext2tex is popular among many users. This style requires the package Pygments to be installed. On Debian Linux,

```
sudo apt-get install python-pygments
```

Alternatively, the package can be installed manually:

```
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
```

If you use the minted style together with ptex2tex, you have to enable it by the -DMINTED command-line argument to ptex2tex. This is not necessary if you run the alternative doconce ptex2tex program.

All use of the minted style requires the -shell-escape command-line argument when running LaTeX, i.e., latex -shell-escape or pdflatex -shell-escape.

5.2.3 reStructuredText (reST) Output

The rst output from Doconce allows further transformation to LaTeX, HTML, XML, OpenOffice, and so on, through the docutils package. The installation of the most recent version can be done by

```
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
cd docutils
sudo python setup.py install
cd ..
```

To use the OpenOffice suite you will typically on Debian systems install

```
sudo apt-get install unovonv libreoffice libreoffice-dmaths
```

There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is rst2pdf. Either download the tarball or clone the svn repository, go to the rst2pdf directory and run the usual sudo python setup.py install.

Output to sphinx requires of course the Sphinx software, installed by

```
hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
cd ..
```

5.2.4 Markdown and Pandoc Output

The Doconce format pandoc outputs the document in the Pandoc extended Markdown format, which via the pandoc program can be translated to a range of other formats. Installation of Pandoc, written in Haskell, is most easily done by

```
sudo apt-get install pandoc
```

5.2.5 Epydoc Output

When the output format is epydoc one needs that program too, installed by

```
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ...
```

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install.

Doconce: Document Once, Include Anywhere

Hans Petter Langtangen [1, 2]

- [1] Simula Research Laboratory
- [2] University of Oslo

Date: Dec 26, 2012

- * When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- * Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX (http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf), HTML (http://www.htmlcodetutorial.com/), reStructuredText (http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html), Sphinx (http://sphinx.pocoo.org/contents.html), and wiki (http://code.google.com/p/support/wiki/WikiSyntax)? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

* Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

The Doconce Concept

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information.

 Text is written in a single place and then transformed to
 a number of different destinations of diverse type (software
 source code, manuals, tutorials, books, wikis, memos, emails, etc.).

The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- * Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- * Doconce can be converted to plain *untagged* text, often desirable for computer programs and email.
- * Doconce has good support for copying in parts of computer code directly from the source code files via regular expressions for the start and end lines.
- * Doconce has full support for LaTeX math and integrates well with big LaTeX projects (books).
- * Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- * Contrary to the similar (and superior) Pandoc translator, Doconce supports Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- * Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- * Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- * Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax

may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- * Bullet lists arise from lines starting with an asterisk.
- * *Emphasized words* are surrounded by asterisks.
- * _Words in boldface_ are surrounded by underscores.
- * Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- * Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- * Paragraph headings are recognized by a double underscore before and after the heading.
- * The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- * Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- * Blocks of computer code can also be imported from source files.
- * Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- * There is support for both LaTeX and text-like inline mathematics.
- * Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- * Invisible comments in the output format can be inserted throughout the text.
- * Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- * There is special support for advanced exercises features.
- * With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.

* With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format::

==== A Subsection with Sample Text =====
label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl"

If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments of the form [name: comment] (with a space after 'name:'), e.g., such as [hpl: here I will make some remarks to the text]. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
	' 	<u></u>

lines beginning with # are comment lines

The Doconce text above results in the following little document:

A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have numbered items instead of bullets, just use an o (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in hpl (http://folk.uio.no/hpl). If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section "A Subsection with Sample Text".

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section "From Doconce to Other Formats" for an example).

Tables are also supperted, e.g.,

=========	========	========
time	velocity	acceleration
========	========	=========
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624

Mathematics and Computer Code

Inline mathematics, such as $v = \sin(x)$, allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like $v = \sin(x)$ is typeset as:

$$\ln = \sin(x)$$
 $v = \sin(x)$

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula. If you write a lot of mathematics, only the output formats latex, pdflatex, html, sphinx, and pandoc are of interest

and all these support inline LaTeX mathematics so then you will naturally drop the pipe symbol and write just::

 $\ln = \sin(x)$

However, if you want more textual formats, like plain text or reStructuredText, the text after the pipe symbol may help to make the math formula more readable if there are backslahes or other special LaTeX symbols in the LaTeX code.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions. The result looks like this::

```
\begin{align}
{\partial u\over\partial t} &= \nabla^2 u + f, label{myeq1}\\
{\partial v\over\partial t} &= \nabla\cdot(q(u)\nabla v) + g
\end{align}
```

Of course, such blocks only looks nice in formats with support for LaTeX mathematics, and here the align environment in particular (this includes latex, pdflatex, html, and sphinx). The raw LaTeX syntax appears in simpler formats, but can still be useful for those who can read LaTeX syntax.

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks are formatted as::

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)
```

import integrate I = integrate.trapezoidal(myfunc, 0, pi, 100)

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments)::

sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of

avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style *newcommand* construction. The newcommands defined in a file with name newcommand_replace.tex are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names newcommands.tex and newcommands keep.tex are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by !bt and !et in newcommands_keep.tex to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in newcommands_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands*.tex files *must* appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page (https://doconce.googlecode.com/hg/doc/demos/manual/index.html) for various formats of this document).

From Doconce to Other Formats

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format::

Terminal > doconce format format mydoc.do.txt

or just::

Terminal> doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example:

Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5 # pre process

Terminal> doconce format latex yourdoc extra_sections=True VAR1=5 # mak

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

The command-line arguments --no-preprocess and --no-make turn off running preprocess and make, respectively.

Inline comments in the text are removed from the output by::

Terminal> doconce format latex mydoc --skip_inline_comments

One can also remove all such comments from the original Doconce file by running::

Terminal> doconce remove_inline_comments mydoc

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

HTML

Making an HTML version of a Doconce file mydoc.do.txt is performed by::

Terminal > doconce format html mydoc

The resulting file mydoc.html can be loaded into any web browser for viewing.

The HTML style is defined in the header of the file. The default style has blue section headings and white background. With the --html-solarized command line argument, the solarized (http://ethanschoonover.com/solarized) color palette is used.

If the Pygments package (including the pygmentize program) is installed, code blocks are typeset with aid of this package. The command-line argument --no-pygments-html turns off the use of Pygments and makes code blocks appear with

plain (pre) HTML tags. The option --pygments-html-linenos turns on line numbers in Pygments-formatted code blocks.

The HTML file can be embedded in a template if the Doconce document does not have a title (because then there will be no header and footer in the HTML file). The template file must contain valid HTML code and can have three "slots": %(title)s for a title, %(date)s for a date, and %(main)s for the main body of text, i.e., the Doconce document translated to HTML. The title becomes the first heading in the Doconce document, and the date is extracted from the DATE: line, if present. With the template feature one can easily embed the text in the look and feel of a website. The template can be extracted from the source code of a page at the site; just insert %(title)s and %(date)s at appropriate places and replace the main bod of text by %(main)s. Here is an example:

Terminal > doconce format html mydoc --html-template=mytemplate.html

Pandoc and Markdown

Output in Pandoc's extended Markdown format results from::

Terminal> doconce format pandoc mydoc

The name of the output file is mydoc.mkd. From this format one can go to numerous other formats::

Terminal> pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it, while the --toc option generates a table of contents. See the Pandoc documentation (http://johnmacfarlane.net/pandoc/README.html) for the many features of the pandoc program.

Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word. There are two ways (experiment to find the best one for your document): doconce format pandoc and then translating using pandoc, or doconce format latex, and then going from LaTeX to the desired format using pandoc.

Here is an example on the latter strategy::

Terminal> doconce format latex mydoc Terminal> doconce ptex2tex mydoc Terminal> pandoc -f latex -t docx -o mydoc.docx mydoc.tex

When we go through pandoc, only single equations or align* environments are well understood.

Quite some doconce replace and doconce subst edits might be needed on the .mkd or .tex files to successfully have mathematics that is well translated to MS Word. Also when going to reStructuredText using

Pandoc, it can be advantageous to go via LaTeX.

Here is an example where we take a Doconce snippet (without title, author, and date), maybe with some unnumbered equations, and quickly generate HTML with mathematics displayed my MathJax::

Terminal> doconce format pandoc mydoc
Terminal> pandoc -t html -o mydoc.html -s --mathjax mydoc.mkd

The -s option adds a proper header and footer to the mydoc.html file. This recipe is a quick way of makeing HTML notes with (some) mathematics.

LaTeX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps:

Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for the ptex2tex program (or doconce ptex2tex)::

Terminal> doconce format latex mydoc

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands_keep.tex, or newcommands_replace.tex (see the section "Macros (Newcommands), Cross-References, Index, and Bibliography").

If these files are present, they are included in the LaTeX document so that your commands are defined.

An option --latex-printed makes some adjustments for documents aimed at being printed. For example, links to web resources are associated with a footnote listing the complete web address (URL).

Step 2. Run ptex2tex (if you have it) to make a standard LaTeX file::

Terminal> ptex2tex mydoc

In case you do not have ptex2tex, you may run a (very) simplified version::

Terminal> doconce ptex2tex mydoc

Note that Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run::

Terminal> ptex2tex -DHELVETICA mydoc
Terminal> doconce ptex2tex mydoc -DHELVETICA # alternative

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading

is also available through -DLATEX_HEADING=traditional. A separate titlepage can be generate by -DLATEX_HEADING=titlepage.

Preprocessor variables to be defined or undefined are

- * BOOK for the "book" documentclass rather than the standard "article" class (necessary if you apply chapter headings)
- * PALATINO for the Palatino font
- * HELVETIA for the Helvetica font
- * A4PAPER for A4 paper size
- * A6PAPER for A6 paper size (suitable for reading on small devices)
- * MOVIE15 for using the movie15 LaTeX package to display movies
- * PREAMBLE to turn the LaTeX preamble on or off (i.e., complete document or document to be included elsewhere)
- * MINTED for inclusion of the minted package (which requires latex or pdflatex to be run with the -shell-escape option)

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc sys for a terminal session, where sys is set to a certain environment in .ptex2tex.cfg (e.g., CodeTerminal). There are about 40 styles to choose from, and you can easily add new ones.

Also the doconce ptex2tex command supports preprocessor directives for processing the .p.tex file. The command allows specifications of code environments as well. Here is an example::

fpro=minted fcod=minted shcod=Verbatim envir=ans:nt

Note that @ must be used to separate the begin and end LaTeX commands, unless only the environment name is given (such as minted above, which implies \begin{minted} {fortran} and \end{minted} as begin and end for blocks inside !bc fpro and !ec). Specifying envir=ans:nt means that all other environments are typeset with the anslistings.sty package, e.g., !bc cppcod will then result in \begin{c++}. If no environments like sys, fpro, or the common envir are defined on the command line, the plain \begin{verbatim} and \end{verbatim} used.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section* to avoid numbering of sections, you may want to insert linebreaks

(and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples::

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

Step 3. Compile mydoc.tex and create the PDF file::

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to run ptex2tex and use the minted LaTeX package for typesetting code blocks (Minted_Python, Minted_Cpp, etc., in ptex2tex specified through the *pro and *cod variables in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LaTeX package is needed. This package is included by running ptex2tex with the -DMINTED option::

Terminal> ptex2tex -DMINTED mydoc

In this case, latex must be run with the -shell-escape option::

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

When running doconce ptex2tex mydoc envir=minted (or other minted specifications with doconce ptex2tex), the minted package is automatically included so there is no need for the -DMINTED option.

```
PDFLaTeX
```

Running pdflatex instead of latex follows almost the same steps, but the start is::

Terminal> doconce format latex mydoc

Then ptex2tex is run as explained above, and finally::

```
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
```

Terminal> pdflatex -shell-escape mydoc

Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code::

Terminal > doconce format plain mydoc.do.txt # results in mydoc.txt

reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst::

Terminal> doconce format rst mydoc.do.txt

We may now produce various other formats::

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports *on the command line*. Run::

Terminal> unoconv --show

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF::

Terminal> unoconv -f ooxml mydoc.odt

Terminal> unoconv -f doc mydoc.odt Terminal> unoconv -f pdf mydoc.odt

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- * http://ubuntuforums.org/showthread.php?t=1033441
- * http://tug.org/utilities/texconv/textopc.html
- * http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx_dir command::

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs::

Terminal > doconce sphinx_dir mydoc

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx_dir command generates a script automake_sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake_sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

The doconce sphinx_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake_sphinx.py must be edited accordingly. Files, to which there are local links (not http: or file: URLs), must be placed in the _static subdirectory of the Sphinx directory. The

utility doconce sphinxfix_localURLs is run to check for local links in the Doconce file: for each such link, say dir1/dir2/myfile.txt it replaces the link by _static/myfile.txt and copies dir1/dir2/myfile.txt to a local _static directory (in the same directory as the script is run). However, we recommend instead that the writer of the document places files in _static or lets a script do it automatically. The user must copy all _static/* files to the _static subdirectory of the Sphinx directory. It may be wise to always put files, to which there are local links in the Doconce document, in a _static or _static-name directory and use these local links. Then links do not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the conf.py configuration file for Sphinx is edited accordingly, and a script make-themes.sh can make HTML documents with one or more themes. For example,

to realize the themes fenics and pyramid, one writes::

Terminal> ./make-themes.sh fenics pyramid

The resulting directories with HTML documents are _build/html_fenics and _build/html_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format::

Terminal> doconce format sphinx mydoc

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter::

mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
n

Name of My Sphinx Document
Author
version
version
.rst
index
n
y
n
n
n
n</pre>

```
tutorial.txt
        У
        n
        n
        У
        У
        У
        EOF
The autogenerated conf.py file
may need some edits if you want to specific layout (Sphinx themes)
of HTML pages. The doconce sphinx_dir generator makes an extended conv.py
file where, among other things, several useful Sphinx extensions
are included.
*Step 3.* Copy the mydoc.rst file to the Sphinx root directory::
        Terminal> cp mydoc.rst sphinx-rootdir
If you have figures in your document, the relative paths to those will
be invalid when you work with mydoc.rst in the sphinx-rootdir
directory. Either edit mydoc.rst so that figure file paths are correct,
or simply copy your figure directories to sphinx-rootdir.
Links to local files in mydoc.rst must be modified to links to
files in the _static directory, see comment above.
*Step 4.* Edit the generated index.rst file so that mydoc.rst
is included, i.e., add mydoc to the toctree section so that it becomes::
        .. toctree::
           :maxdepth: 2
           mydoc
(The spaces before mydoc are important!)
*Step 5.* Generate, for instance, an HTML version of the Sphinx source::
        make clean # remove old versions
        make html
Sphinx can generate a range of different formats:
standalone HTML, HTML in separate directories with index.html files,
a large single HTML file, JSON files, various help files (the qthelp, HTML,
and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages,
and Texinfo files.
*Step 6.* View the result::
        Terminal> firefox _build/html/index.html
Note that verbatim code blocks can be typeset in a variety of ways
```

depending the argument that follows !bc: cod gives Python

(code-block:: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

Wiki Formats

There are many different wiki formats, but Doconce only supports three: Googlecode wiki (http://code.google.com/p/support/wiki/WikiSyntax), MediaWiki, and Creole Wiki. These formats are called gwiki, mwiki, and cwiki, respectively. Transformation from Doconce to these formats is done by::

Terminal> doconce format gwiki mydoc.do.txt Terminal> doconce format mwiki mydoc.do.txt Terminal> doconce format cwiki mydoc.do.txt

The Googlecode wiki document, mydoc.gwiki, is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.

When the Doconce file contains figures, each figure filename must in the .gwiki file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

From the MediaWiki format one can go to other formats with aid of mwlib (http://pediapress.com/code/). This means that one can easily use Doconce to write Wikibooks (http://en.wikibooks.org) and publish these in PDF and MediaWiki format. At the same time, the book can also be published as a standard LaTeX book or a Sphinx web document.

Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename.

The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

Demos

The current text is generated from a Doconce format stored in the file::

docs/tutorial/tutorial.do.txt

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here (https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html) is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

Installation of Doconce and its Dependencies

Doconce

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hq) source follows the standard procedure::

Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..

Since Doconce is frequently updated, it is recommended to use the above procedure and whenever a problem occurs, make sure to update to the most recent version::

cd doconce
hg pull
hg update
sudo python setup.py install

Debian GNU/Linux users can also run::

sudo apt-get install doconce

This installs the latest release and not the most updated and bugfixed version.

On Ubuntu one needs to run::

sudo add-apt-repository ppa:scitools/ppa
sudo apt-get update
sudo apt-get install doconce

Dependencies

```
tutorial.txt
Preprocessors
~~~~~~~~~~
If you make use of the Preprocess (http://code.google.com/p/preprocess)
preprocessor, this program must be installed::
       svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
       cd preprocess
       cd doconce
       sudo python setup.py install
       cd ..
A much more advanced alternative to Preprocess is
Mako (http://www.makotemplates.org). Its installation is most
conveniently done by pip::
       pip install Mako
This command requires pip to be installed. On Debian Linux systems,
such as Ubuntu, the installation is simply done by::
        sudo apt-get install python-pip
Alternatively, one can install from the pip source code (http://pypi.python.org/
pypi/pip).
Mako can also be installed directly from
source (http://www.makotemplates.org/download.html): download the
tarball, pack it out, go to the directory and run
the usual sudo python setup.py install.
Ptex2tex for LaTeX Output
To make LaTeX documents with very flexible choice of typesetting of
verbatim code blocks you need ptex2tex (http://code.google.com/p/ptex2tex),
which is installed by::
       svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
       cd ptex2tex
        sudo python setup.py install
It may happen that you need additional style files, you can run
a script, cp2texmf.sh::
       cd latex
       sh cp2texmf.sh # copy stylefiles to ~/texmf directory
       cd ../..
This script copies some special stylefiles that
that ptex2tex potentially makes use of. Some more standard stylefiles
```

are also needed. These are installed by::

sudo apt-get install texlive-latex-recommended texlive-latex-extra

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the ~/texmf/tex/latex/misc directory).

Note that the doconce ptex2tex command, which needs no installation beyond Doconce itself, can be used as a simpler alternative to the ptex2tex program.

The *minted* LaTeX style is offered by ptex2tex and doconce ptext2tex is popular among many users. This style requires the package Pygments (http://pygments.org) to be installed. On Debian Linux::

sudo apt-get install python-pygments

Alternatively, the package can be installed manually::

hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments cd pygments sudo python setup.py install

If you use the minted style together with ptex2tex, you have to enable it by the -DMINTED command-line argument to ptex2tex. This is not necessary if you run the alternative doconce ptex2tex program.

All

use of the minted style requires the -shell-escape command-line argument when running LaTeX, i.e., latex -shell-escape or pdflatex -shell-escape.

reStructuredText (reST) Output

The rst output from Doconce allows further transformation to LaTeX, HTML, XML, OpenOffice, and so on, through the docutils (http://docutils.sourceforge.net) package. The installation of the most recent version can be done by::

svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/
docutils

cd docutils
sudo python setup.py install
cd ..

To use the OpenOffice suite you will typically on Debian systems install::

sudo apt-qet install unovonv libreoffice libreoffice-dmaths

There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is rst2pdf (http://code.google.com/p/rst2pdf). Either download the tarball or clone the svn repository, go to the rst2pdf directory and run the usual sudo python setup.py install.

Output to sphinx requires of course the Sphinx software (http://sphinx.pocoo.org), installed by::

hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
cd ..

Markdown and Pandoc Output

The Doconce format pandoc outputs the document in the Pandoc extended Markdown format, which via the pandoc program can be translated to a range of other formats. Installation of Pandoc (http://johnmacfarlane.net/pandoc/), written in Haskell, is most easily done by::

svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc ep

sudo apt-get install pandoc

Epydoc Output

When the output format is epydoc one needs that program too, installed by::

ydoc

cd epydoc
sudo make install
cd ..

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install.

"

TITLE: Doconce: Document Once, Include Anywhere

BY: Hans Petter Langtangen (Simula Research Laboratory, and University of Oslo)D ATE: today

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?

- Do you need to write documents in varying formats but find it
 difficult to remember all the typesetting details of various
 formats like U{LaTeX<http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCar
d.v2.0.pdf>}, U{HTML<http://www.htmlcodetutorial.com/>}, U{reStructuredText<http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html>}, U{Sphinx<http://sphinx.pocoo.org/contents.html>}, and U{wiki<http://code.google.com/p/support/wiki/WikiSyntax>}? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

The Doconce Concept

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via C{rst2*} programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via C{unoconv}) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain I {untagged} text,

- often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code directly from the source code files via regular expressions for the start and end lines.
- Doconce has full support for LaTeX math and integrates well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- Contrary to the similar (and superior) Pandoc translator, Doconce supports Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- I{Emphasized words} are surrounded by asterisks.
- B{Words in boldface} are surrounded by underscores.
- Words from computer code are enclosed in back quotes and

then typeset C{verbatim (in a monospace font)}.

- Section headings are recognied by equality (C{=}) signs before and after the title, and the number of $C\{=\}$ signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with I{Abstract} as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing C{!bc} (begin code) and C{!ec} (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.Blocks of LaTeX mathematics can easily be included by placing C{!bt} (begin TeX) and C{!et} (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables,
 - URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format::

```
===== A Subsection with Sample Text =====
label{my:first:sec}
```

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl"

If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments of the form [name: comment] (with a space after 'name:'), e.g., such as [hpl: here I will make some remarks to the text]. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
		·

lines beginning with # are comment lines

The Doconce text above results in the following little document:

A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for $B\{boldface\}$ words, $I\{emphasized\}$ words, and $C\{computer\}$ words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an $C\{o\}$ (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in U{hpl<http://folk.uio.no/hpl>}. If the word is URL, the URL itself becomes the link name, as in U{tutorial.do.txt<tutorial.do.txt>}.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section "A Subsection with Sample Text".

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section "From Doconce to Other Formats" for an example).

Tables are also supperted, e.g.,

========	========	=========
time	velocity	acceleration
========	=========	=========
0.0 2.0	1.4186 1.376512	-5.01 11.919

4.0 1.1E+1 14.717624

Mathematics and Computer Code

Inline mathematics, such as $M\{v=\sin(x)\}$, allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like $M\{v=\sin(x)\}$ is typeset as:

NOTE: A verbatim block has been removed because it causes problems for Epytext.

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula. If you write a lot of mathematics, only the output formats C{latex}, C{pdflatex}, C{html}, C{sphinx}, and C{pandoc} are of interest and all these support inline LaTeX mathematics so then you will naturally

and all these support inline LaTeX mathematics so then you will naturally drop the pipe symbol and write just::

NOTE: A verbatim block has been removed because it causes problems for Epytext.

However, if you want more textual formats, like plain text or reStructuredText, the text after the pipe symbol may help to make the math formula more readable if there are backslahes or other special LaTeX symbols in the LaTeX code.

Blocks of mathematics are better typeset with raw LaTeX, inside $C\{!bt\}$ and $C\{!et\}$ (begin tex / end tex) instructions. The result looks like this::

NOTE: A verbatim block has been removed because it causes problems for Epytext.

Of course, such blocks only looks nice in formats with support for LaTeX mathematics, and here the align environment in particular (this includes C{latex}, C{pdflatex}, C{html}, and C{sphinx}). The raw LaTeX syntax appears in simpler formats, but can still be useful for those who can read LaTeX syntax.

You can have blocks of computer code, starting and ending with C{!bc} and C{!ec} instructions, respectively. Such blocks are formatted as::

from math import sin, pi
def myfunc(x):
 return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)

A code block must come after some plain sentence (at least for successful output to C{sphinx}, C{rst}, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., C{!bc xxx} where C{xxx} is an identifier like C{pycod} for code snippet in Python, C{sys} for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in C{ptex2tex} and defined in a configuration file C{.ptext2tex.cfg}, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments)::

sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, $C\{pro\}$ and $C\{cod\}$ are $C\{python\}$, $C\{sys\}$ is $C\{console\}$, while $C\{xpro\}$ and $C\{xcod\}$ are computer language specific for $C\{x\}$ in $C\{f\}$ (Fortran), $C\{c\}$ (C), $C\{cpp\}$ (C++), $C\{pl\}$ (Perl), $C\{m\}$ (Matlab), $C\{sh\}$ (Unix shells), $C\{cy\}$ (Cython), and $C\{py\}$ (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with C{!bc pro}, while a part of a file is copied into a C{!bc cod} environment. What C{pro} and C{cod} mean is then defined through a C{.ptex2tex.cfg} file for LaTeX and a C{sphinx code-blocks} comment for Sphinx.

Another document can be included by writing $C\{\# include \# mynote.do.txt"\}$ on a line starting with (another) hash sign. Doconce documents have extension $C\{do.txt\}$. The $C\{do\}$ part stands for doconce, while the trailing $C\{.txt\}$ denotes a text document so that editors gives you the right writing environment for plain text.

Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style I{newcommand} construction. The newcommands defined in a file with name C{newcommand_replace.tex} are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names C{newcommands.tex} and C{newcommands_keep.tex} are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by C{!bt} and C{!et} in C{newcommands_keep.tex} to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in

 $C\{\text{newcommands_replace.tex}\}\$ and expanded by Doconce. The definitions of newcommands in the $C\{\text{newcommands*.tex}\}\$ files $I\{\text{must}\}\$ appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the C{doc/manual/manual.do.txt} file (see the U{demo page<https://doconce.googlecode.com/hg/doc/demos/manual/index.html>} for various formats of this document).

From Doconce to Other Formats

Transformation of a Doconce document $C\{mydoc.do.txt\}$ to various other formats applies the script $C\{doconce\ format\}:$

Terminal> doconce format format mydoc.do.txt

or just::

Terminal > doconce format format mydoc

The $C\{mako\}$ or $C\{preprocess\}$ programs are always used to preprocess the file first, and options to $C\{mako\}$ or $C\{preprocess\}$ can be added after the filename. For example:

Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5 # pre process

Terminal> doconce format latex yourdoc extra_sections=True VAR1=5 # mak o

The variable C{FORMAT} is always defined as the current format when running C{preprocess}. That is, in the last example, C{FORMAT} is defined as C{latex}. Inside the Doconce document one can then perform format specific actions through tests like C{#if FORMAT == "latex"}.

The command-line arguments $C\{--no-preprocess\}$ and $C\{--no-mako\}$ turn off running $C\{preprocess\}$ and $C\{mako\}$, respectively.

Inline comments in the text are removed from the output by::

Terminal> doconce format latex mydoc --skip_inline_comments

One can also remove all such comments from the original Doconce

file by running::

Terminal> doconce remove_inline_comments mydoc

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

 HTML

Making an HTML version of a Doconce file C{mydoc.do.txt} is performed by::

Terminal> doconce format html mydoc

The resulting file C{mydoc.html} can be loaded into any web browser for viewing.

The HTML style is defined in the header of the file. The default style has blue section headings and white background. With the $C\{--html-solarized\}$ command line argument, the $U\{solarized < http://ethanschoonover.com/solarized > \}$ color palette is used.

If the Pygments package (including the C{pygmentize} program) is installed, code blocks are typeset with aid of this package. The command-line argument C{--no-pygments-html} turns off the use of Pygments and makes code blocks appear with plain (C{pre}) HTML tags. The option C{--pygments-html-linenos} turns on line numbers in Pygments-formatted code blocks.

The HTML file can be embedded in a template if the Doconce document does not have a title (because then there will be no header and footer in the HTML file). The template file must contain valid HTML code and can have three "slots": $C\{\$(\text{title})s\}$ for a title, $C\{\$(\text{date})s\}$ for a date, and $C\{\$(\text{main})s\}$ for the main body of text, i.e., the Doconce document translated to HTML. The title becomes the first heading in the Doconce document, and the date is extracted from the $C\{\text{DATE}:\}$ line, if present. With the template feature one can easily embed the text in the look and feel of a website. The template can be extracted from the source code of a page at the site; just insert $C\{\$(\text{title})s\}$ and $C\{\$(\text{date})s\}$ at appropriate places and replace the main bod of text by $C\{\$(\text{main})s\}$. Here is an example:

Terminal > doconce format html mydoc --html-template=mytemplate.html

Pandoc and Markdown

randoc ana narmaown

Output in Pandoc's extended Markdown format results from::

Terminal> doconce format pandoc mydoc

The name of the output file is C{mydoc.mkd}. From this format one can go to numerous other formats::

Terminal> pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd

Pandoc supports $C\{latex\}$, $C\{html\}$, $C\{odt\}$ (OpenOffice), $C\{docx\}$ (Microsoft Word), $C\{rtf\}$, $C\{texinfo\}$, to mention some. The $C\{-R\}$ option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it, while the $C\{--toc\}$ option generates a table of contents. See the $U\{Pandoc\ documentation<http://johnmacfarlane.net/pandoc/README.html>\} for the many features of the <math>C\{pandoc\}$ program.

Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word. There are two ways (experiment to find the best one for your document): $C\{doconce\ format\ pandoc\}\ and\ then\ translating\ using\ C\{pandoc\}\ ,$ or $C\{doconce\ format\ latex\}\ ,$ and then going from LaTeX to the desired format using $C\{pandoc\}\ .$

Here is an example on the latter strategy::

Terminal> doconce format latex mydoc Terminal> doconce ptex2tex mydoc Terminal> pandoc -f latex -t docx -o mydoc.docx mydoc.tex

When we go through C{pandoc}, only single equations or C{align*} environments are well understood.

Quite some $C\{doconce\ replace\}$ and $C\{doconce\ subst\}$ edits might be needed on the $C\{.mkd\}$ or $C\{.tex\}$ files to successfully have mathematics that is well translated to MS Word. Also when going to reStructuredText using Pandoc, it can be advantageous to go via LaTeX.

Here is an example where we take a Doconce snippet (without title, author, and date), maybe with some unnumbered equations, and quickly generate HTML with mathematics displayed my MathJax::

Terminal> doconce format pandoc mydoc
Terminal> pandoc -t html -o mydoc.html -s --mathjax mydoc.mkd

The $C\{-s\}$ option adds a proper header and footer to the $C\{mydoc.html\}$ file. This recipe is a quick way of makeing HTML notes with (some) mathematics.

LaTeX

Making a LaTeX file C{mydoc.tex} from C{mydoc.do.txt} is done in two steps:

I{Step 1.} Filter the doconce text to a pre-LaTeX form $C\{mydoc.p.tex\}$ for the $C\{ptex2tex\}$ program (or $C\{doconce\ ptex2tex\}$)::

Terminal> doconce format latex mydoc

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files C{newcommands.tex}, C{newcommands_keep.tex}, or C{newcommands_replace.tex} (see the section "Macros (Newcommands), Cross-Referen ces, Index, and Bibliography").
If these files are present, they are included in the LaTeX document

so that your commands are defined.

An option C{--latex-printed} makes some adjustments for documents aimed at being printed. For example, links to web resources are associated with a footnote listing the complete web address (URL).

I{Step 2.} Run C{ptex2tex} (if you have it) to make a standard LaTeX file::

Terminal> ptex2tex mydoc

In case you do not have C{ptex2tex}, you may run a (very) simplified version::

Terminal > doconce ptex2tex mydoc

Note that Doconce generates a C{.p.tex} file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run::

> Terminal> ptex2tex -DHELVETICA mydoc Terminal > doconce ptex2tex mydoc -DHELVETICA # alternative

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through C{-DLATEX_HEADING=traditional}. A separate titlepage can be generate by C{-DLATEX_HEADING=titlepage}.

Preprocessor variables to be defined or undefined are

- C{BOOK} for the "book" documentclass rather than the standard "article" class (necessary if you apply chapter headings)
- C{PALATINO} for the Palatino font
 C{HELVETIA} for the Helvetica font
- C(A4PAPER) for A4 paper size
 C(A6PAPER) for A6 paper size (suitable for reading on small devices)
- C{MOVIE15} for using the movie15 LaTeX package to display movies
- C{PREAMBLE} to turn the LaTeX preamble on or off (i.e., complete document or document to be included elsewhere)
- C{MINTED} for inclusion of the minted package (which requires C{latex} or C{pdflatex} to be run with the C{-shell-escape} option)

The C{ptex2tex} tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any C{!bc} command in the Doconce source you can insert verbatim block styles as defined in your C{.ptex2tex.cfg} file, e.g., C{!bc sys} for a terminal session, where C{sys} is set to a certain environment in C{.ptex2tex.cfg} (e.g., C{CodeTerminal}). There are about 40 styles to choose from, and you can easily add new ones.

Also the $C\{doconce\ ptex2tex\}$ command supports preprocessor directives for processing the $C\{.p.tex\}$ file. The command allows specifications of code environments as well. Here is an example::

fpro=minted fcod=minted shcod=Verbatim envir=ans:nt

Note that $C\{@\}$ must be used to separate the begin and end LaTeX commands, unless only the environment name is given (such as $C\{\text{minted}\}$ above, which implies $C\{\text{begin}\{\text{minted}\}\{\text{fortran}\}\}$ and $C\{\text{end}\{\text{minted}\}\}$ as begin and end for blocks inside $C\{\text{!bc fpro}\}$ and $C\{\text{!ec}\}$). Specifying $C\{\text{envir=ans:nt}\}$ means that all other environments are typeset with the $C\{\text{anslistings.sty}\}$ package, e.g., $C\{\text{!bc cppcod}\}$ will then result in $C\{\text{begin}\{\text{c++}\}\}$. If no environments like $C\{\text{sys}\}$, $C\{\text{fpro}\}$, or the common $C\{\text{envir}\}$ are defined on the command line, the plain $C\{\text{begin}\{\text{verbatim}\}\}$ and $C\{\text{end}\{\text{verbatim}\}\}$ used.

I{Step 2b (optional).} Edit the C{mydoc.tex} file to your needs. For example, you may want to substitute C{section} by C{section*} to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the C{doconce replace} and C{doconce subst} commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples::

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

I{Step 3.} Compile C{mydoc.tex}
and create the PDF file::

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to run $C\{ptex2tex\}$ and use the minted LaTeX package for typesetting code blocks ($C\{Minted_Python\}$, $C\{Minted_Cpp\}$, etc., in $C\{ptex2tex\}$ specified through the $C\{*pro\}$ and $C\{*cod\}$ variables in $C\{.ptex2tex.cfg\}$ or $C\{$HOME/.ptex2tex.cfg\}$), the minted LaTeX package is needed. This package is included by running $C\{ptex2tex\}$ with the $C\{-DMINTED\}$ option::

Terminal> ptex2tex -DMINTED mydoc

```
tutorial.epytext
In this case, C{latex} must be run with the
C{-shell-escape} option::
        Terminal> latex -shell-escape mydoc
        Terminal> latex -shell-escape mydoc
        Terminal> makeindex mydoc # if index
        Terminal> bibitem mydoc
                                      # if bibliography
        Terminal> latex -shell-escape mydoc
        Terminal> dvipdf mydoc
When running C{doconce ptex2tex mydoc envir=minted} (or other minted
specifications with C\{doconce\ ptex2tex\}), the minted package is automatically included so there is no need for the C\{-DMINTED\} option.
PDFLaTeX
Running C{pdflatex} instead of C{latex} follows almost the same steps,
but the start is::
        Terminal> doconce format latex mydoc
Then C{ptex2tex} is run as explained above, and finally::
        Terminal> pdflatex -shell-escape mydoc
        Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
        Terminal> pdflatex -shell-escape mydoc
Plain ASCII Text
We can go from Doconce "back to" plain untagged text suitable for viewing
in terminal windows, inclusion in email text, or for insertion in
computer source code::
        Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
reStructuredText
Going from Doconce to reStructuredText gives a lot of possibilities to
go to other formats. First we filter the Doconce text to a
reStructuredText file C{mydoc.rst}::
        Terminal> doconce format rst mydoc.do.txt
We may now produce various other formats::
```

```
tutorial.epytext
        Terminal> rst2html.py mydoc.rst > mydoc.html # html
        Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
        Terminal> rst2xml.py
                               mydoc.rst > mydoc.xml # XML
                               mydoc.rst > mydoc.odt # OpenOffice
        Terminal> rst2odt.py
The OpenOffice file C{mydoc.odt} can be loaded into OpenOffice and
saved in, among other things, the RTF format or the Microsoft Word format.
However, it is more convenient to use the program C{unovonv}
to convert between the many formats OpenOffice supports I (on the command line).
Run::
        Terminal> unoconv --show
to see all the formats that are supported.
For example, the following commands take
C{mydoc.odt} to Microsoft Office Open XML format,
classic MS Word format, and PDF::
        Terminal> unoconv -f ooxml mydoc.odt
        Terminal> unoconv -f doc mydoc.odt
        Terminal> unoconv -f pdf mydoc.odt
I{Remark about Mathematical Typesetting.} At the time of this writing, there is
no easy way to go from Doconce
and LaTeX mathematics to reST and further to OpenOffice and the
"MS Word world". Mathematics is only fully supported by C\{latex\} as output and to a wide extent also supported by the C\{sphinx\} output format.
Some links for going from LaTeX to Word are listed below.
 - U{http://ubuntuforums.org/showthread.php?t=1033441<http://ubuntuforums.org/sh
owthread.php?t=1033441>}
 - U{http://tug.org/utilities/texconv/textopc.html<http://tug.org/utilities/texc
onv/textopc.html>}
 - U{http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html<http:
//nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html>}
Sphinx
Sphinx documents demand quite some steps in their creation. We have automated
most of the steps through the C{doconce sphinx_dir} command::
        theme=mytheme file1 file2 file3 ...
The keywords C{author}, C{title}, and C{version} are used in the headings
of the Sphinx document. By default, C{version} is 1.0 and the script
will try to deduce authors and title from the doconce files C{file1},
C{file2}, etc. that together represent the whole document. Note that
none of the individual Doconce files C{file1}, C{file2}, etc. should
include the rest as their union makes up the whole document.
```

The default value of C{dirname} is C{sphinx-rootdir}. The C{theme} keyword is used to set the theme for design of HTML output from

Sphinx (the default theme is C{'default'}).

With a single-file document in C{mydoc.do.txt} one often just runs::

Terminal > doconce sphinx dir mydoc

and then an appropriate Sphinx directory C{sphinx-rootdir} is made with relevant files.

The C{doconce sphinx_dir} command generates a script C{automake_sphinx.py} for compiling the Sphinx document into an HTML document. One can either run C{automake_sphinx.py} or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

The C{doconce sphinx_dir} script copies directories named C{figs} or C{figures} over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, C{automake_sphinx.py} must be edited accordingly. Files, to which there are local links (not C{http:} or C{file:} URLs), must be placed in the C{_static} subdirectory of the Sphinx directory. The utility C{doconce sphinxfix_localURLs} is run to check for local links in the Doconce file: for each such link, say C{dir1/dir2/myfile.txt} it replaces the link by C{_static/myfile.txt} and copies C{dir1/dir2/myfile.txt} to a local C{_static} directory (in the same directory as the script is run). However, we recommend instead that the writer of the document places files in C{_static} or lets a script do it automatically. The user must copy all C{_static/*} files to the C{_static} subdirectory of the Sphinx directory. It may be wise to always put files, to which there are local links in the Doconce document, in a C{_static} or C{_static-name} directory and use these local links. Then links do not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the $C\{conf.py\}$ configuration file for Sphinx is edited accordingly, and a script $C\{make-themes.sh\}$ can make HTML documents with one or more themes. For example,

to realize the themes C{fenics} and C{pyramid}, one writes::

Terminal> ./make-themes.sh fenics pyramid

The resulting directories with HTML documents are C{_build/html_fenics} and C{_build/html_pyramid}, respectively. Without arguments, C{make-themes.sh} makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file C{mydoc.do.txt}.

I{Step 1.} Translate Doconce into the Sphinx format::

Terminal> doconce format sphinx mydoc

(The spaces before C{mydoc} are important!)

I{Step 5.} Generate, for instance, an HTML version of the Sphinx source::

make clean # remove old versions
make html

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with C{index.html} files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

I{Step 6.} View the result::

Terminal> firefox _build/html/index.html

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows $C\{!bc\}$: $C\{cod\}$ gives Python ($C\{code-block::python\}$ in Sphinx syntax) and $C\{cppcod\}$ gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

Wiki Formats

There are many different wiki formats, but Doconce only supports three: U{Googlecode wiki<http://code.google.com/p/support/wiki/WikiSyntax>}, MediaWiki, and Creole Wiki. These formats are called C{gwiki}, C{mwiki}, and C{cwiki}, respectively. Transformation from Doconce to these formats is done by::

Terminal> doconce format gwiki mydoc.do.txt Terminal> doconce format mwiki mydoc.do.txt Terminal> doconce format cwiki mydoc.do.txt

The Googlecode wiki document, C{mydoc.gwiki}, is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.

When the Doconce file contains figures, each figure filename must in the C{.gwiki} file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

From the MediaWiki format one can go to other formats with aid of U{mwlib<http://pediapress.com/code/>}. This means that one can easily use Doconce to write U{Wikibooks<http://en.wikibooks.org>} and publish these in PDF and MediaWiki format.
At the same time, the book can also be published as a standard LaTeX book or a Sphinx web document.

Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the $C\{.rst\}$ file is going to be filtered to LaTeX or HTML, it cannot know if $C\{.eps\}$ or $C\{.png\}$ is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The $C\{make.sh\}$ files in $C\{docs/manual\}$ and $C\{docs/tutorial\}$ constitute comprehensive examples on how such scripts can be made.

Demos

The current text is generated from a Doconce format stored in the file::

docs/tutorial/tutorial.do.txt

The file C{make.sh} in the C{tutorial} directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, C{tutorial.do.txt} is the starting point. Running C{make.sh} and studying the various generated files and comparing them with the original C{tutorial.do.txt} file, gives a quick introduction to how Doconce is used in a real case. U{Here<https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html>} is a sample of how this tutorial looks in different formats.

There is another demo in the $C\{docs/manual\}$ directory which translates the more comprehensive documentation, $C\{manual.do.txt\}$, to various formats. The $C\{make.sh\}$ script runs a set of translations.

Installation of Doconce and its Dependencies

Doconce

Doconce itself is pure Python code hosted at $U\{\text{http://code.google.com/p/doconce} \land \text{http://code.google.com/p/doconce}\}$. Its installation from the Mercurial ($C\{\text{hg}\}$) source follows the standard procedure::

Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..

Since Doconce is frequently updated, it is recommended to use the above procedure and whenever a problem occurs, make sure to update to the most recent version::

```
tutorial.epytext
        cd doconce
        hg pull
        hq update
        sudo python setup.py install
Debian GNU/Linux users can also run::
        sudo apt-get install doconce
This installs the latest release and not the most updated and bugfixed
version.
On Ubuntu one needs to run::
        sudo add-apt-repository ppa:scitools/ppa
        sudo apt-get update
        sudo apt-get install doconce
Dependencies
Preprocessors
~~~~~~~~~~
If you make use of the U{Preprocess<http://code.google.com/p/preprocess>}
preprocessor, this program must be installed::
        svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
        cd preprocess
        cd doconce
        sudo python setup.py install
        cd ..
A much more advanced alternative to Preprocess is
U{Mako<http://www.makotemplates.org>}. Its installation is most
conveniently done by C{pip}::
        pip install Mako
This command requires C{pip} to be installed. On Debian Linux systems,
such as Ubuntu, the installation is simply done by::
        sudo apt-get install python-pip
Alternatively, one can install from the C{pip} U{source code<a href="http://pypi.python.">http://pypi.python.</a>
org/pypi/pip>}.
Mako can also be installed directly from
U{source<http://www.makotemplates.org/download.html>}: download the
tarball, pack it out, go to the directory and run
the usual C{sudo python setup.py install}.
```

Ptex2tex for LaTeX Output

To make LaTeX documents with very flexible choice of typesetting of verbatim code blocks you need U{ptex2tex<http://code.google.com/p/ptex2tex>}, which is installed by::

svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install

It may happen that you need additional style files, you can run a script, C{cp2texmf.sh}::

cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..

This script copies some special stylefiles that that C{ptex2tex} potentially makes use of. Some more standard stylefiles are also needed. These are installed by::

sudo apt-get install texlive-latex-recommended texlive-latex-extra

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the $C{\sim/\text{texmf/tex/latex/misc}}$ directory).

Note that the $C\{doconce\ ptex2tex\}$ command, which needs no installation beyond Doconce itself, can be used as a simpler alternative to the $C\{ptex2tex\}$ program.

The I{minted} LaTeX style is offered by C{ptex2tex} and C{doconce ptext2tex} is popular among many users. This style requires the package U{Pygmentshttp://pygments.org} to be installed. On Debian Linux::

sudo apt-get install python-pygments

Alternatively, the package can be installed manually::

hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments cd pygments sudo python setup.py install

If you use the minted style together with $C\{ptex2tex\}$, you have to enable it by the $C\{-DMINTED\}$ command-line argument to $C\{ptex2tex\}$. This is not necessary if you run the alternative $C\{doconce\ ptex2tex\}$ program.

All

use of the minted style requires the C{-shell-escape} command-line argument when running LaTeX, i.e., C{latex -shell-escape} or C{pdflatex

```
tutorial.epytext
-shell-escape \}.
reStructuredText (reST) Output
The C{rst} output from Doconce allows further transformation to LaTeX,
HTML, XML, OpenOffice, and so on, through the U{docutils<http://docutils.sourcef
orge.net>} package. The installation of the
most recent version can be done by::
        svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/
docutils
        cd docutils
        sudo python setup.py install
To use the OpenOffice suite you will typically on Debian systems install::
        sudo apt-get install unovonv libreoffice libreoffice-dmaths
There is a possibility to create PDF files from reST documents
using ReportLab instead of LaTeX. The enabling software is
U{rst2pdf<http://code.google.com/p/rst2pdf>}. Either download the tarball
or clone the svn repository, go to the C{rst2pdf} directory and
run the usual C{sudo python setup.py install}.
Output to C{sphinx} requires of course the
U{Sphinx software<http://sphinx.pocoo.org>},
installed by::
        hg clone https://bitbucket.org/birkenfeld/sphinx
        cd sphinx
        sudo python setup.py install
        cd ..
Markdown and Pandoc Output
The Doconce format C{pandoc} outputs the document in the Pandoc
extended Markdown format, which via the C{pandoc} program can be translated to a range of other formats. Installation of U{Pandoc<http://johnmacf
arlane.net/pandoc/>), written in Haskell, is most
easily done by::
        sudo apt-get install pandoc
Epydoc Output
When the output format is C{epydoc} one needs that program too, installed
```

```
Printed by hpl
                                                     tutorial.epytext
by::
             svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc ep
ydoc
             cd epydoc
             sudo make install
             cd ..
I{Remark.} Several of the packages above installed from source code are also available in Debian-based system through the C{apt-get install} command. However, we recommend installation directly
from the version control system repository as there might be important updates and bug fixes. For C{svn} directories, go to the directory, run C{svn update}, and then C{sudo python setup.py install}. For
Mercurial (C{hg}) directories, go to the directory, run
C{hg pull; hg update}, and then C{sudo python setup.py install}.
```

"

#summary Doconce: Document Once, Include Anywhere

By *Hans Petter Langtangen*

==== Dec 26, 2012 ====

- * When writing a note, report, manual, etc., do you find it difficult to choo se the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- ly go with a particular format?

 * Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like [http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf LaTeX], [http://www.htmlcodet utorial.com/ HTML], [http://docutils.sourceforge.net/docs/ref/rst/restructuredte xt.html reStructuredText], [http://sphinx.pocoo.org/contents.html Sphinx], and [http://code.google.com/p/support/wiki/WikiSyntax wiki]? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- * Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

== The Doconce Concept ==

Doconce is two things:

Doconce is a very simple and minimally tagged markup language that looks l ike ordinary ASCII text (much like what you would use in an email), but the t ext can be transformed to numerous other formats, including HTML, Pandoc, Goo gle wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plai formatting/tags are removed for clear reading in, e n text (where non-obvious emails). From reST you can (via 'rst2*' programs) go to XML, HTML, TeX, PDF, OpenOffice, and from the latter (via 'unoconv') to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. Markdown, reST, LaTeX, HTML, PDF, DocBook XML, From Pandoc one can generate penOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats. # Doconce is a working strategy for never duplicating information. OpenOffice, GNU

Doconce is a working strategy for never duplicating information. Text is w ritten in a single place and then transformed to a number of different destin ations of diverse type (software source code, manuals, tutorials, books, wiki s, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- * Doconce markup does include tags, so the format is more tagged than Markd own and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- * Doconce can be converted to plain *untagged* text, often desirable for computer programs and email.
- * Doconce has good support for copying in parts of computer code directly f rom the source code files via regular expressions for the start and end lines

- * Doconce has full support for LaTeX math and integrates well with big LaTe X projects (books).
- * Doconce is almost self-explanatory and is a handy starting point for gene rating documents in more complicated markup languages, such as Google wiki, L aTeX, and Sphinx. A primary application of Doconce is just to make the initia l versions of a Sphinx or wiki document.
- * Contrary to the similar (and superior) Pandoc translator, Doconce support s Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- * Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- * Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for u se with Sphinx, as wiki text when publishing the software at web sites, and a s LaTeX integrated in, e.g., a thesis.
- * Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

== What Does Doconce Look Like? ==

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- * Bullet lists arise from lines starting with an asterisk.
- * *Emphasized words* are surrounded by asterisks.
- * *Words in boldface* are surrounded by underscores.
- * Words from computer code are enclosed in back quotes and then typeset 've rbatim (in a monospace font)'.
- * Section headings are recognied by equality ('=') signs before and after the title, and the number of '=' signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.

- * Paragraph headings are recognized by a double underscore before and after the heading.
- * The abstract of a document starts with *Abstract* as paragraph heading, a nd all text up to the next heading makes up the abstract,
- * Blocks of computer code can easily be included by placing '!bc' (begin co de) and '!ec' (end code) commands at separate lines before and after the code block.
 - * Blocks of computer code can also be imported from source files.
- * Blocks of LaTeX mathematics can easily be included by placing '!bt' (begin TeX) and '!et' (end TeX) commands at separate lines before and after the math block.
 - * There is support for both LaTeX and text-like inline mathematics.
- * Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- * Invisible comments in the output format can be inserted throughout $\,$ the text.
- * Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
 - * There is special support for advanced exercises features.
- * With a simple preprocessor, Preprocess or Mako, one can include other doc uments (files) and large portions of text can be defined in or out of the text.
 - * With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format: $\{\{\{\}\}\}$

==== A Subsection with Sample Text ===== label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments of the form [name: comment] (with a space after 'name:'), e.g., such as [hpl: here I will make some remarks to the text]. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

lines beginning with # are comment lines
}}}

The Doconce text above results in the following little document:

==== A Subsection with Sample Text ====

Ordinary text looks like ordinary text, and the tags used for *boldface* words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have numbered items instead of bullets, just use an 'o' (for ordered) instead of the asterisk:

- # item 1
- # item 2
- # item 3

URLs with a link word are possible, as in [http://folk.uio.no/hpl hpl]. If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section [#A_Subsection_with_Sample_Text].

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section [#From_Doconce_to_Other_Formats] for an example).

Tables are also supperted, e.g.,

==== Mathematics and Computer Code ====

Inline mathematics, such as 'v = sin(x)', allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with

```
tutorial.gwiki
backslashes. An inline formula like v = \sin(x) is
typeset as
\ln = \sin(x) v = \sin(x)
} } }
The pipe symbol acts as a delimiter between LaTeX code and the plain text
version of the formula. If you write a lot of mathematics, only the
output formats 'latex', 'pdflatex', 'html', 'sphinx', and 'pandoc'
are of interest
and all these support inline LaTeX mathematics so then you will naturally
drop the pipe symbol and write just
{{{
$\nu = \sin(x)$
} } }
However, if you want more textual formats, like plain text or reStructuredText,
the text after the pipe symbol may help to make the math formula more readable
if there are backslahes or other special LaTeX symbols in the LaTeX code.
Blocks of mathematics are better typeset with raw LaTeX, inside
'!bt' and '!et' (begin tex / end tex) instructions.
The result looks like this:
{ { {
\begin{align}
{\partial u\over\partial t} &= \nabla^2 u + f, label{myeq1}\\
{\partial v\over\partial t} &= \nabla\cdot(q(u)\nabla v) + g
\end{align}
} } }
Of course, such blocks only looks nice in formats with support
for LaTeX mathematics, and here the align environment in particular
(this includes 'latex', 'pdflatex', 'html', and 'sphinx'). The raw
LaTeX syntax appears in simpler formats, but can still be useful
for those who can read LaTeX syntax.
You can have blocks of computer code, starting and ending with
'!bc' and '!ec' instructions, respectively. Such blocks are formatted as
from math import sin, pi
def myfunc(x):
    return sin(pi*x)
import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
} } }
A code block must come after some plain sentence (at least for successful
output to 'sphinx', 'rst', and ASCII-close formats), not directly after a section/paragraph heading or a table.
It is possible to add a specification of an
environment for typesetting the verbatim code block, e.g., '!bc xxx'
where 'xxx' is an identifier like 'pycod' for code snippet in Python,
'sys' for terminal session, etc. When Doconce is filtered to LaTeX,
these identifiers are used as in 'ptex2tex' and defined in a
configuration file `.ptext2tex.cfg`, while when filtering
to Sphinx, one can have a comment line in the Doconce file for
mapping the identifiers to legal language names for Sphinx (which equals
```

the legal language names for Pygments):

{{{

sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
}}}

By default, 'pro' and 'cod' are 'python', 'sys' is 'console',
while 'xpro' and 'xcod' are computer language specific for 'x'
in 'f' (Fortran), 'c' (C), 'cpp' (C++), 'pl' (Perl), 'm' (Matlab),
'sh' (Unix shells), 'cy' (Cython), and 'py' (Python).

<wiki:comment> (Any sphinx code-block comment, whether inside verbatim code </wi>
ki:comment>

<wiki:comment> blocks or outside, yields a mapping between bc arguments </wiki:c
omment>

<wiki:comment> and computer languages. In case of muliple definitions, the </wik
i:comment>

<wiki:comment> first one is used.) </wiki:comment>

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with '!bc pro', while a part of a file is copied into a '!bc cod' environment. What 'pro' and 'cod' mean is then defined through a '.ptex2tex.cfg' file for LaTeX and a 'sphinx code-blocks' comment for Sphinx.

Another document can be included by writing '#include "mynote.do.txt"' on a line starting with (another) hash sign. Doconce documents have extension 'do.txt'. The 'do' part stands for doconce, while the trailing '.txt' denotes a text document so that editors gives you the right writing environment for plain text.

==== Macros (Newcommands), Cross-References, Index, and Bibliography ====

Doconce supports a type of macros via a LaTeX-style *newcommand* construction. The newcommands defined in a file with name 'newcommand_replace.tex' are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names 'newcommands.tex' and 'newcommands_keep.tex' are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by '!bt' and '!et' in 'newcommands_keep.tex' to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in 'newcommands_replace.tex' and expanded by Doconce. The definitions of newcommands in the 'newcommands*.tex' files *must* appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references,

```
tutorial.gwiki
citations, and the bibliography closely resembles that of LaTeX,
making it easy for Doconce documents to be integrated in LaTeX
projects (manuals, books). For further details on functionality and
syntax we refer to the 'doc/manual/manual.do.txt' file (see the
[https://doconce.googlecode.com/hg/doc/demos/manual/index.html demo page]
for various formats of this document).
<wiki:comment> Example on including another Doconce file (using preprocess): </wr>
iki:comment>
== From Doconce to Other Formats ==
Transformation of a Doconce document 'mydoc.do.txt' to various other
formats applies the script 'doconce format':
Terminal> doconce format format mydoc.do.txt
} } }
or just
{ { {
Terminal > doconce format format mydoc
The 'mako' or 'preprocess' programs are always used to preprocess the file first, and options to 'mako' or 'preprocess' can be added after the
filename. For example,
{{{
Terminal > doconce format latex mydoc -Dextra_sections -DVAR1=5
                                                                            # preprocess
Terminal > doconce format latex yourdoc extra_sections=True VAR1=5 # mako
}}}
The variable 'FORMAT' is always defined as the current format when running 'preprocess'. That is, in the last example, 'FORMAT' is defined as 'latex'. Inside the Doconce document one can then perform
format specific actions through tests like '#if FORMAT == "latex"'.
The command-line arguments '--no-preprocess' and '--no-mako' turn off
running 'preprocess' and 'mako', respectively.
Inline comments in the text are removed from the output by
{ { {
Terminal > doconce format latex mydoc --skip_inline_comments
One can also remove all such comments from the original Doconce
file by running:
{ { {
Terminal > doconce remove_inline_comments mydoc
This action is convenient when a Doconce document reaches its final form
and comments by different authors should be removed.
==== HTML ====
Making an HTML version of a Doconce file 'mydoc.do.txt'
is performed by
{ { {
Terminal > doconce format html mydoc
} } }
The resulting file 'mydoc.html' can be loaded into any web browser for viewing.
```

```
The HTML style is defined in the header of the file. The default style
has blue section headings and white background. With the '--html-solarized'
command line argument, the [http://ethanschoonover.com/solarized solarized]
color palette is used.
If the Pygments package (including the 'pygmentize' program)
is installed, code blocks are typeset with
aid of this package. The command-line argument '--no-pygments-html'
turns off the use of Pygments and makes code blocks appear with
plain ('pre') HTML tags. The option '--pygments-html-linenos' turns
on line numbers in Pygments-formatted code blocks.
The HTML file can be embedded in a template if the Doconce document
does not have a title (because then there will be
no header and footer in the HTML file). The template file must contain
valid HTML code and can have three "slots": '%(title)s' for a title,
'%(date)s' for a date, and '%(main)s' for the main body of text, i.e., the
Doconce document translated to HTML. The title becomes the first
heading in the Doconce document, and the date is extracted from the
'DATE: ' line, if present. With the template feature one can easily embed
the text in the look and feel of a website. The template can be extracted
from the source code of a page at the site; just insert '%(title)s' and
'%(date)s' at appropriate places and replace the main bod of text
by '%(main)s'. Here is an example:
{ { {
Terminal > doconce format html mydoc --html-template=mytemplate.html
} } }
==== Pandoc and Markdown ====
Output in Pandoc's extended Markdown format results from
Terminal > doconce format pandoc mydoc
The name of the output file is 'mydoc.mkd'.
From this format one can go to numerous other formats:
Terminal > pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd
Pandoc supports 'latex', 'html', 'odt' (OpenOffice), 'docx' (Microsoft
Word), 'rtf', 'texinfo', to mention some. The '-R' option makes
Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it,
while the '--toc' option generates a table of contents.
See the [http://johnmacfarlane.net/pandoc/README.html Pandoc documentation]
for the many features of the 'pandoc' program.
Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word.
There are two ways (experiment to find the best one for your document):
'doconce format pandoc' and then translating using 'pandoc', or 'doconce format latex', and then going from LaTeX to the desired format
using 'pandoc'.
Here is an example on the latter strategy:
```

,,

Terminal> doconce format latex mydoc Terminal> doconce ptex2tex mydoc

}}

Terminal > pandoc -f latex -t docx -o mydoc.docx mydoc.tex

When we go through 'pandoc', only single equations or 'align*'

tutorial.gwiki environments are well understood.

Quite some 'doconce replace' and 'doconce subst' edits might be needed Pandoc, it can be advantageous to go via LaTeX.

```
on the '.mkd' or '.tex' files to successfully have mathematics that is
well translated to MS Word. Also when going to reStructuredText using
Here is an example where we take a Doconce snippet (without title, author,
and date), maybe with some unnumbered equations, and quickly generate
HTML with mathematics displayed my MathJax:
Terminal > doconce format pandoc mydoc
Terminal > pandoc -t html -o mydoc.html -s --mathjax mydoc.mkd
} } }
The '-s' option adds a proper header and footer to the 'mydoc.html' file.
This recipe is a quick way of makeing HTML notes with (some) mathematics.
==== LaTeX ====
Making a LaTeX file 'mydoc.tex' from 'mydoc.do.txt' is done in two steps:
<wiki:comment> Note: putting code blocks inside a list is not successful in many
 </wiki:comment>
<wiki:comment> formats - the text may be messed up. A better choice is a paragra
ph </wiki:comment>
<wiki:comment> environment, as used here. </wiki:comment>
*Step 1.* Filter the doconce text to a pre-LaTeX form 'mydoc.p.tex' for
the 'ptex2tex' program (or 'doconce ptex2tex'):
Terminal> doconce format latex mydoc
} } }
LaTeX-specific commands ("newcommands") in math formulas and similar
can be placed in files 'newcommands.tex', 'newcommands_keep.tex', or
'newcommands_replace.tex' (see the section [#Macros_(Newcommands),_Cross-Referen
ces,_Index,_and_Bibliography]).
If these files are present, they are included in the LaTeX document
so that your commands are defined.
An option '--latex-printed' makes some adjustments for documents
aimed at being printed. For example, links to web resources are
associated with a footnote listing the complete web address (URL).
*Step 2.* Run 'ptex2tex' (if you have it) to make a standard LaTeX file,
Terminal> ptex2tex mydoc
} } }
In case you do not have 'ptex2tex', you may run a (very) simplified version:
Terminal > doconce ptex2tex mydoc
}}}
Note that Doconce generates a '.p.tex' file with some preprocessor macros
that can be used to steer certain properties of the LaTeX document.
For example, to turn on the Helvetica font instead of the standard
Computer Modern font, run
Terminal> ptex2tex -DHELVETICA mydoc
Terminal > doconce ptex2tex mydoc -DHELVETICA # alternative
```

} } }

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through '-DLATEX HEADING=traditional'. A separate titlepage can be generate by '-DLATEX HEADING=titlepage'.

Preprocessor variables to be defined or undefined are

- * 'BOOK' for the "book" documentclass rather than the standard "article" clas s (necessary if you apply chapter headings)

 - * 'PALATINO' for the Palatino font

 * 'HELVETIA' for the Helvetica font
 - * 'A4PAPER' for A4 paper size
 - * 'A6PAPER' for A6 paper size (suitable for reading on small devices)
 - * 'MOVIE15' for using the movie15 LaTeX package to display movies
 - * 'PREAMBLE' to turn the LaTeX preamble on or off (i.e., complete document or document to be included elsewhere)
- * 'MINTED' for inclusion of the minted package (which requires 'latex' or 'pd flatex' to be run with the '-shell-escape' option)

The 'ptex2tex' tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any '!bc' command in the Doconce source you can insert verbatim block styles as defined in your '.ptex2tex.cfg' file, e.g., '!bc sys' for a terminal session, where 'sys' is set to a certain environment in '.ptex2tex.cfg' (e.g., 'CodeTerminal'). There are about 40 styles to choose from, and you can easily add new ones.

Also the 'doconce ptex2tex' command supports preprocessor directives for processing the '.p.tex' file. The command allows specifications of code environments as well. Here is an example: { { {

Terminal> doconce ptex2tex mydoc -DLATEX_HEADING=traditional \ -DPALATINO -DA6PAPER \

"sys=\begin{quote}\begin{verbatim}@\end{verbatim}\end{quote}" \ fpro=minted fcod=minted shcod=Verbatim envir=ans:nt

Note that '@' must be used to separate the begin and end LaTeX commands, unless only the environment name is given (such as 'minted' above, which implies '\begin{minted}{fortran}' and '\end{minted}' as begin and end for blocks inside '!bc fpro' and '!ec'). Specifying 'envir=ans:nt' means that all other environments are typeset with the 'anslistings.sty' package, e.g., '!bc cppcod' will then result in '\begin{c++}'. If no environments like 'sys', 'fpro', or the common 'envir' are defined on the command line, the plain '\begin{verbatim}' and '\end{verbatim}' used.

Step 2b (optional). Edit the 'mydoc.tex' file to your needs. For example, you may want to substitute 'section' by 'section' to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the 'doconce replace' and 'doconce subst' commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples:

```
tutorial.gwiki
{ { {
Terminal> doconce replace 'section{' 'section*{' mydoc.tex
Terminal > doconce subst 'title\\{(.+)Using (.+)\\\\\\\
          'title{\q<1> \\\ [1.5mm] Using \q<2>' mydoc.tex
A lot of tailored fixes to the LaTeX document can be done by
an appropriate set of text replacements and regular expression
substitutions. You are anyway encourged to make a script for
generating PDF from the LaTeX file.
*Step 3.* Compile 'mydoc.tex'
and create the PDF file:
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
} } }
If one wishes to run 'ptex2tex' and use the minted LaTeX package for
typesetting code blocks ('Minted_Python', 'Minted_Cpp', etc., in
'ptex2tex' specified through the '*pro' and '*cod' variables in
'.ptex2tex.cfg' or '$HOME/.ptex2tex.cfg'), the minted LaTeX package is
needed. This package is included by running 'ptex2tex' with the
'-DMINTED' option:
Terminal> ptex2tex -DMINTED mydoc
} } }
In this case, 'latex' must be run with the
'-shell-escape' option:
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
When running 'doconce ptex2tex mydoc envir=minted' (or other minted
specifications with 'doconce ptex2tex'), the minted package is automatically
included so there is no need for the '-DMINTED' option.
==== PDFLaTeX ====
Running 'pdflatex' instead of 'latex' follows almost the same steps,
but the start is
{ { {
Terminal> doconce format latex mydoc
} } }
Then 'ptex2tex' is run as explained above, and finally
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc
                            # if bibliography
Terminal> pdflatex -shell-escape mydoc
} } }
```

```
tutorial.gwiki
==== Plain ASCII Text ====
We can go from Doconce "back to" plain untagged text suitable for viewing
in terminal windows, inclusion in email text, or for insertion in
computer source code:
{ { {
Terminal > doconce format plain mydoc.do.txt # results in mydoc.txt
} } }
==== reStructuredText ====
Going from Doconce to reStructuredText gives a lot of possibilities to
go to other formats. First we filter the Doconce text to a
reStructuredText file 'mydoc.rst':
Terminal> doconce format rst mydoc.do.txt
}}}
We may now produce various other formats:
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py
                        mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py
                        mydoc.rst > mydoc.odt # OpenOffice
}}}
The OpenOffice file 'mydoc.odt' can be loaded into OpenOffice and
saved in, among other things, the RTF format or the Microsoft Word format.
However, it is more convenient to use the program 'unovonv'
to convert between the many formats OpenOffice supports *on the command line*.
Run
{ { {
Terminal> unoconv --show
} } }
to see all the formats that are supported.
For example, the following commands take
'mydoc.odt' to Microsoft Office Open XML format,
classic MS Word format, and PDF:
Terminal> unoconv -f ooxml mydoc.odt
Terminal > unoconv -f doc mydoc.odt
Terminal > unoconv -f pdf mydoc.odt
} } }
*Remark about Mathematical Typesetting.* At the time of this writing, there is n
o easy way to go from Doconce
and LaTeX mathematics to reST and further to OpenOffice and the
"MS Word world". Mathematics is only fully supported by 'latex' as output and to a wide extent also supported by the 'sphinx' output format.
Some links for going from LaTeX to Word are listed below.
 * http://ubuntuforums.org/showthread.php?t=1033441
 * http://tug.org/utilities/texconv/textopc.html
 * http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html
==== Sphinx ====
Sphinx documents demand quite some steps in their creation. We have automated
most of the steps through the 'doconce sphinx dir' command:
```

```
tutorial.gwiki
{ { {
Terminal> doconce sphinx_dir author="authors' names" \
          title="some title" version=1.0 dirname=sphinxdir \
          theme=mytheme file1 file2 file3 ...
The keywords 'author', 'title', and 'version' are used in the headings
of the Sphinx document. By default, 'version' is 1.0 and the script
will try to deduce authors and title from the doconce files 'file1',
'file2', etc. that together represent the whole document. Note that
none of the individual Doconce files 'file1', 'file2', etc. should
include the rest as their union makes up the whole document.
The default value of 'dirname' is 'sphinx-rootdir'. The 'theme'
keyword is used to set the theme for design of HTML output from
Sphinx (the default theme is ''default'').
With a single-file document in 'mydoc.do.txt' one often just runs
Terminal > doconce sphinx_dir mydoc
} } }
and then an appropriate Sphinx directory 'sphinx-rootdir' is made with
relevant files.
The 'doconce sphinx dir' command generates a script
'automake_sphinx.py' for compiling the Sphinx document into an HTML
document. One can either run 'automake_sphinx.py' or perform the
steps in the script manually, possibly with necessary modifications.
You should at least read the script prior to executing it to have
some idea of what is done.
The 'doconce sphinx_dir' script copies directories named 'figs' or
'figures' over to the Sphinx directory so that figures are accessible
in the Sphinx compilation. If figures or movies are located in other directories, 'automake_sphinx.py' must be edited accordingly. Files,
to which there are local links (not 'http:' or 'file:' URLs), must be
placed in the '_static' subdirectory of the Sphinx directory. The
utility 'doconce sphinxfix_localURLs' is run to check for local links
in the Doconce file: for each such link, say 'dir1/dir2/myfile.txt' it
replaces the link by '_static/myfile.txt' and copies
'dir1/dir2/myfile.txt' to a local '_static' directory (in the same
directory as the script is run). However, we recommend instead that
the writer of the document places files in '_static' or lets a script
do it automatically. The user must copy all '_static/*' files to the
'_static' subdirectory of the Sphinx directory. It may be wise to
always put files, to which there are local links in the Doconce
document, in a '_static' or '_static-name' directory and use these
local links. Then links do not need to be modified when creating a
Sphinx version of the document.
Doconce comes with a collection of HTML themes for Sphinx documents.
These are packed out in the Sphinx directory, the 'conf.py'
configuration file for Sphinx is edited accordingly, and a script
'make-themes.sh' can make HTML documents with one or more themes.
For example,
to realize the themes 'fenics' and 'pyramid', one writes
{ { {
Terminal> ./make-themes.sh fenics pyramid
The resulting directories with HTML documents are '_build/html_fenics'
```

and '_build/html_pyramid', respectively. Without arguments,

```
tutorial.gwiki
'make-themes.sh' makes all available themes (!).
If it is not desirable to use the autogenerated scripts explained
above, here is the complete manual procedure of generating a
Sphinx document from a file 'mydoc.do.txt'.
*Step 1.* Translate Doconce into the Sphinx format:
Terminal > doconce format sphinx mydoc
} } }
*Step 2.* Create a Sphinx root directory
either manually or by using the interactive 'sphinx-quickstart' program. Here is a scripted version of the steps with the latter:
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
Name of My Sphinx Document
version
version
.rst
index
n
У
n
n
n
n
У
n
n
У
У
У
EOF
} } }
The autogenerated 'conf.py' file
may need some edits if you want to specific layout (Sphinx themes)
of HTML pages. The 'doconce sphinx_dir' generator makes an extended 'conv.py' file where, among other things, several useful Sphinx extensions
are included.
*Step 3.* Copy the 'mydoc.rst' file to the Sphinx root directory:
{ { {
Terminal> cp mydoc.rst sphinx-rootdir
If you have figures in your document, the relative paths to those will
be invalid when you work with 'mydoc.rst' in the 'sphinx-rootdir'
directory. Either edit 'mydoc.rst' so that figure file paths are correct,
or simply copy your figure directories to 'sphinx-rootdir'.
Links to local files in 'mydoc.rst' must be modified to links to
files in the '_static' directory, see comment above.
*Step 4.* Edit the generated 'index.rst' file so that 'mydoc.rst'
```

```
tutorial.gwiki
is included, i.e., add 'mydoc' to the 'toctree' section so that it becomes
{ { {
.. toctree::
   :maxdepth: 2
   mydoc
} } }
(The spaces before 'mydoc' are important!)
*Step 5.* Generate, for instance, an HTML version of the Sphinx source:
              # remove old versions
make clean
make html
}}}
Sphinx can generate a range of different formats:
standalone HTML, HTML in separate directories with 'index.html' files,
a large single HTML file, JSON files, various help files (the qthelp, HTML,
and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages,
and Texinfo files.
*Step 6.* View the result:
Terminal> firefox build/html/index.html
} } }
Note that verbatim code blocks can be typeset in a variety of ways
depending the argument that follows '!bc': 'cod' gives Python
('code-block: python' in Sphinx syntax) and 'cppcod' gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.
==== Wiki Formats ====
There are many different wiki formats, but Doconce only supports three:
[http://code.google.com/p/support/wiki/WikiSyntax Googlecode wiki], MediaWiki, a
nd Creole Wiki. These formats are called
'gwiki', 'mwiki', and 'cwiki', respectively.
Transformation from Doconce to these formats is done by
{ { {
Terminal > doconce format gwiki mydoc.do.txt
Terminal > doconce format mwiki mydoc.do.txt
Terminal > doconce format cwiki mydoc.do.txt
}}}
The Googlecode wiki document, 'mydoc.gwiki', is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project.
This is far easier than copying and pasting the entire text into the wiki editor in a web browser.
When the Doconce file contains figures, each figure filename must in
the '.gwiki' file be replaced by a URL where the figure is
available. There are instructions in the file for doing this. Usually,
one performs this substitution automatically (see next section).
From the MediaWiki format one can go to other formats with aid
of [http://pediapress.com/code/ mwlib]. This means that one can
easily use Doconce to write [http://en.wikibooks.org Wikibooks]
and publish these in PDF and MediaWiki format.
At the same time, the book can also be published as a
```

sudo python setup.py install

```
tutorial.gwiki
}}}
Debian GNU/Linux users can also run
{{{
sudo apt-get install doconce
}}}
This installs the latest release and not the most updated and bugfixed
version.
On Ubuntu one needs to run
{ { {
sudo add-apt-repository ppa:scitools/ppa
sudo apt-get update
sudo apt-get install doconce
} } }
==== Dependencies ====
==== Preprocessors ====
If you make use of the [http://code.google.com/p/preprocess Preprocess]
preprocessor, this program must be installed:
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
cd ..
}}}
A much more advanced alternative to Preprocess is
[http://www.makotemplates.org Mako]. Its installation is most
conveniently done by 'pip',
{ { {
pip install Mako
} } }
This command requires 'pip' to be installed. On Debian Linux systems,
such as Ubuntu, the installation is simply done by
{ { {
sudo apt-get install python-pip
Alternatively, one can install from the 'pip' [http://pypi.python.org/pypi/pip s
ource code].
Mako can also be installed directly from
[http://www.makotemplates.org/download.html source]: download the
tarball, pack it out, go to the directory and run
the usual 'sudo python setup.py install'.
==== Ptex2tex for LaTeX Output ====
To make LaTeX documents with very flexible choice of typesetting of
verbatim code blocks you need [http://code.google.com/p/ptex2tex ptex2tex],
which is installed by
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
```

```
tutorial.gwiki
cd ptex2tex
sudo python setup.py install
} } }
It may happen that you need additional style files, you can run
a script, 'cp2texmf.sh':
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
} } }
This script copies some special stylefiles that
that 'ptex2tex' potentially makes use of. Some more standard stylefiles are also needed. These are installed by
{ { {
sudo apt-get install texlive-latex-recommended texlive-latex-extra
on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with
the necessary stylefiles (if not, they can be found by googling and installed
manually in the '~/texmf/tex/latex/misc' directory).
Note that the 'doconce ptex2tex' command, which needs no installation
beyond Doconce itself, can be used as a simpler alternative to the 'ptex2tex'
program.
The *minted* LaTeX style is offered by 'ptex2tex' and 'doconce ptext2tex'
is popular among many
users. This style requires the package [http://pygments.org Pygments]
to be installed. On Debian Linux,
{ { {
sudo apt-get install python-pygments
} } }
Alternatively, the package can be installed manually:
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
}}}
If you use the minted style together with 'ptex2tex', you have to
enable it by the '-DMINTED' command-line argument to 'ptex2tex'.
This is not necessary if you run the alternative 'doconce ptex2tex' program.
All
use of the minted style requires the '-shell-escape' command-line
argument when running LaTeX, i.e., 'latex -shell-escape' or 'pdflatex
-shell-escape'.
<wiki:comment> Say something about anslistings.sty </wiki:comment>
==== reStructuredText (reST) Output ====
The 'rst' output from Doconce allows further transformation to LaTeX,
HTML, XML, OpenOffice, and so on, through the [http://docutils.sourceforge.net d
ocutils] package. The installation of the
most recent version can be done by
{ { {
```

```
tutorial.gwiki
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
cd docutils
sudo python setup.py install
cd ..
} } }
To use the OpenOffice suite you will typically on Debian systems install
{ { {
sudo apt-get install unovonv libreoffice libreoffice-dmaths
} } }
There is a possibility to create PDF files from reST documents
using ReportLab instead of LaTeX. The enabling software is [http://code.google.com/p/rst2pdf rst2pdf]. Either download the tarball
or clone the svn repository, go to the 'rst2pdf' directory and
run the usual 'sudo python setup.py install'.
Output to 'sphinx' requires of course the
[http://sphinx.pocoo.org Sphinx software],
installed by
{ { {
hg clone https://bitbucket.org/birkenfeld/sphinx
sudo python setup.py install
cd ..
} } }
==== Markdown and Pandoc Output ====
The Doconce format 'pandoc' outputs the document in the Pandoc
extended Markdown format, which via the 'pandoc' program can be translated to a range of other formats. Installation of [http://johnmacfarlane.n
et/pandoc/ Pandoc], written in Haskell, is most
easily done by
{ { {
sudo apt-get install pandoc
}}}
==== Epydoc Output ====
When the output format is 'epydoc' one needs that program too, installed
by
\{\bar{\{}\}\}
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ..
} } }
*Remark.* Several of the packages above installed from source code
are also available in Debian-based system through the
'apt-get install' command. However, we recommend installation directly
from the version control system repository as there might be important
updates and bug fixes. For 'svn' directories, go to the directory,
run 'svn update', and then 'sudo python setup.py install'. For
Mercurial ('hg') directories, go to the directory, run
'hg pull; hg update', and then 'sudo python setup.py install'.
```

" tutorial.md '

- % Doconce: Document Once, Include Anywhere
- % Hans Petter Langtangen at Simula Research Laboratory and University of Oslo
- % Dec 26, 2012
 - * When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- * Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like [LaTeX](http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf), [HTML](http://www.htmlcodetutorial.com/), [reStructuredText](http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html), [Sphinx](http://sphinx.pocoo.org/contents.html), and [wiki](http://code.google.com/p/support/wiki/WikiSyntax)? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

* Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

The Doconce Concept

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via 'rst2*' programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via 'unoconv') to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

* Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than

LaTeX and HTML.

- * Doconce can be converted to plain *untagged* text, often desirable for computer programs and email.
- * Doconce has good support for copying in parts of computer code directly from the source code files via regular expressions for the start and end lines.
- * Doconce has full support for LaTeX math and integrates well with big LaTeX projects (books).
- * Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- * Contrary to the similar (and superior) Pandoc translator, Doconce supports Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- * Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- * Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- * Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- * Bullet lists arise from lines starting with an asterisk.
- * *Emphasized words* are surrounded by asterisks.
- * _Words in boldface_ are surrounded by underscores.
- * Words from computer code are enclosed in back quotes and then typeset 'verbatim (in a monospace font)'.
- * Section headings are recognied by equality ('=') signs before and after the title, and the number of '=' signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- * Paragraph headings are recognized by a double underscore before and after the heading.
- * The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- * Blocks of computer code can easily be included by placing '!bc' (begin code) and '!ec' (end code) commands at separate lines before and after the code block.
- * Blocks of computer code can also be imported from source files.
- * Blocks of LaTeX mathematics can easily be included by placing '!bt' (begin TeX) and '!et' (end TeX) commands at separate lines before and after the math block.
- * There is support for both LaTeX and text-like inline mathematics.
- * Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- * Invisible comments in the output format can be inserted throughout the text.
- * Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- * There is special support for advanced exercises features.
- * With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- * With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

==== A Subsection with Sample Text =====
\label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments of the form [name: comment] (with a space after 'name:'), e.g., such as [hpl: here I will make some remarks to the text]. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
	' 	<u> </u>

lines beginning with # are comment lines

The Doconce text above results in the following little document:

A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for _boldface_ words, *emphasized* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- * item 1
- * item 2
- * item 3

Lists can also have numbered items instead of bullets, just use an 'o' (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in [hpl](http://folk.uio.no/hpl). If the word is URL, the URL itself becomes the link name, as in <tutorial.do.txt>.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section [A Subsection with Sample Text](#t).

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section [From Doconce to Other Formats](#s) for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624

Mathematics and Computer Code

Inline mathematics, such as $nu = \sin(x)$, allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like $nu = \sin(x)$ is typeset as

 $\pi = \sin(x)$ $\pi = \sin(x)$

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula. If you write a lot of mathematics, only the output formats 'latex', 'pdflatex', 'html', 'sphinx', and 'pandoc' are of interest

and all these support inline LaTeX mathematics so then you will naturally drop the pipe symbol and write just

% \nu = \sin(x)\$

```
tutorial.md
However, if you want more textual formats, like plain text or reStructuredText,
the text after the pipe symbol may help to make the math formula more readable
if there are backslahes or other special LaTeX symbols in the LaTeX code.
Blocks of mathematics are better typeset with raw LaTeX, inside
'!bt' and '!et' (begin tex / end tex) instructions.
The result looks like this:
\begin{align}
{\partial u\over\partial t} &= \nabla^2 u + f, \label{myeq1}\\
{\partial v\over\partial t} &= \nabla\cdot(q(u)\nabla v) + g
\end{align}
Of course, such blocks only looks nice in formats with support
for LaTeX mathematics, and here the align environment in particular
(this includes 'latex', 'pdflatex', 'html', and 'sphinx'). The raw LaTeX syntax appears in simpler formats, but can still be useful
for those who can read LaTeX syntax.
You can have blocks of computer code, starting and ending with
'!bc' and '!ec' instructions, respectively. Such blocks are formatted as
from math import sin, pi
def myfunc(x):
    return sin(pi*x)
import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
A code block must come after some plain sentence (at least for successful
output to 'sphinx', 'rst', and ASCII-close formats),
not directly after a section/paragraph heading or a table.
It is possible to add a specification of an
environment for typesetting the verbatim code block, e.g., '!bc xxx'
where 'xxx' is an identifier like 'pycod' for code snippet in Python,
'sys' for terminal session, etc. When Doconce is filtered to LaTeX,
these identifiers are used as in 'ptex2tex' and defined in a configuration file '.ptext2tex.cfg', while when filtering to Sphinx, one can have a comment line in the Doconce file for
mapping the identifiers to legal language names for Sphinx (which equals
the legal language names for Pygments):
# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
By default, 'pro' and 'cod' are 'python', 'sys' is 'console', while 'xpro' and 'xcod' are computer language specific for 'x' in 'f' (Fortran), 'c' (C), 'cpp' (C++), 'pl' (Perl), 'm' (Matlab), 'sh' (Unix shells), 'cy' (Cython), and 'py' (Python).
<!-- (Any sphinx code-block comment, whether inside verbatim code -->
<!-- blocks or outside, yields a mapping between bc arguments -->
<!-- and computer languages. In case of muliple definitions, the -->
```

<!-- first one is used.) -->

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with '!bc pro', while a part of a file is copied into a '!bc cod' environment. What 'pro' and 'cod' mean is then defined through a '.ptex2tex.cfg' file for LaTeX and a 'sphinx code-blocks' comment for Sphinx.

Another document can be included by writing '#include "mynote.do.txt"' on a line starting with (another) hash sign. Doconce documents have extension 'do.txt'. The 'do' part stands for doconce, while the trailing '.txt' denotes a text document so that editors gives you the right writing environment for plain text.

Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style *newcommand* construction. The newcommands defined in a file with name 'newcommand replace.tex' are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names 'newcommands.tex' and 'newcommands_keep.tex' are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by '!bt' and '!et' in 'newcommands_keep.tex' to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in 'newcommands_replace.tex' and expanded by Doconce. The definitions of newcommands in the 'newcommands*.tex' files *must* appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the 'doc/manual/manual.do.txt' file (see the [demo page](https://doconce.googlecode.com/hg/doc/demos/manual/index.html) for various formats of this document).

<!-- Example on including another Doconce file (using preprocess): -->

From Doconce to Other Formats

" tutorial.md "
Transformation of a Doconce document 'mydoc.do.txt' to various other formats applies the script 'doconce format':
Terminal> doconce format format mydoc.do.txt
or just
{.Bash} Terminal> doconce format format mydoc
The 'mako' or 'preprocess' programs are always used to preprocess the file first, and options to 'mako' or 'preprocess' can be added after the filename. For example,
<pre>Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5 # preprocess Terminal> doconce format latex yourdoc extra_sections=True VAR1=5 # mako</pre>
The variable 'FORMAT' is always defined as the current format when running 'preprocess'. That is, in the last example, 'FORMAT' is defined as 'latex'. Inside the Doconce document one can then perform format specific actions through tests like '#if FORMAT == "latex"'.
The command-line arguments 'no-preprocess' and 'no-mako' turn off running 'preprocess' and 'mako', respectively.
Inline comments in the text are removed from the output by
Terminal> doconce format latex mydocskip_inline_comments
One can also remove all such comments from the original Doconce file by running:
Terminal> doconce remove_inline_comments mydoc
This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.
HTML
Making an HTML version of a Doconce file 'mydoc.do.txt' is performed by
Terminal> doconce format html mydoc
The resulting file 'mydoc.html' can be loaded into any web browser for viewing.

tutorial.md

The HTML style is defined in the header of the file. The default style has blue section headings and white background. With the '--html-solarized' command line argument, the [solarized](http://ethanschoonover.com/solarized) color palette is used.

If the Pygments package (including the 'pygmentize' program) is installed, code blocks are typeset with aid of this package. The command-line argument '--no-pygments-html' turns off the use of Pygments and makes code blocks appear with plain ('pre') HTML tags. The option '--pygments-html-linenos' turns on line numbers in Pygments-formatted code blocks.

The HTML file can be embedded in a template if the Doconce document does not have a title (because then there will be no header and footer in the HTML file). The template file must contain valid HTML code and can have three "slots": '%(title)s' for a title, '%(date)s' for a date, and '%(main)s' for the main body of text, i.e., the Doconce document translated to HTML. The title becomes the first heading in the Doconce document, and the date is extracted from the 'DATE: ' line, if present. With the template feature one can easily embed the text in the look and feel of a website. The template can be extracted from the source code of a page at the site; just insert '%(title)s' and '%(date)s' at appropriate places and replace the main bod of text by '%(main)s'. Here is an example:

Terminal > doconce format html mydoc --html-template=mytemplate.html

Pandoc and Markdown

Output in Pandoc's extended Markdown format results from

Terminal> doconce format pandoc mydoc

The name of the output file is 'mydoc.mkd'.

From this format one can go to numerous other formats:

Terminal> pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd

Pandoc supports 'latex', 'html', 'odt' (OpenOffice), 'docx' (Microsoft Word), 'rtf', 'texinfo', to mention some. The '-R' option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it, while the '--toc' option generates a table of contents. See the [Pandoc documentation](http://johnmacfarlane.net/pandoc/README.html) for the many features of the 'pandoc' program.

Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word. There are two ways (experiment to find the best one for your document): 'doconce format pandoc' and then translating using 'pandoc', or 'doconce format latex', and then going from LaTeX to the desired format using 'pandoc'.

Here is an example on the latter strategy:

" tutorial.md "
~~~~~~~{.Bash}
Terminal> doconce format latex mydoc Terminal> doconce ptex2tex mydoc Terminal> pandoc –f latex –t docx –o mydoc.docx mydoc.tex ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
When we go through 'pandoc', only single equations or 'align*' environments are well understood.
Quite some 'doconce replace' and 'doconce subst' edits might be needed on the '.mkd' or '.tex' files to successfully have mathematics that is well translated to MS Word. Also when going to reStructuredText using Pandoc, it can be advantageous to go via LaTeX.
Here is an example where we take a Doconce snippet (without title, author, and date), maybe with some unnumbered equations, and quickly generate HTML with mathematics displayed my MathJax:
Towningly decorate format and a mydes
Terminal> doconce format pandoc mydoc Terminal> pandoc –t html –o mydoc.html –s ––mathjax mydoc.mkd
The '-s' option adds a proper header and footer to the 'mydoc.html' file. This recipe is a quick way of makeing HTML notes with (some) mathematics.
LaTeX 
Making a LaTeX file 'mydoc.tex' from 'mydoc.do.txt' is done in two steps: Note: putting code blocks inside a list is not successful in many formats - the text may be messed up. A better choice is a paragraph environment, as used here
*Step 1.* Filter the doconce text to a pre–LaTeX form 'mydoc.p.tex' for the 'ptex2tex' program (or 'doconce ptex2tex'):
~~~~~~~{.Bash}
Terminal> doconce format latex mydoc
LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files 'newcommands.tex', 'newcommands_keep.tex', or 'newcommands_replace.tex' (see the section [Macros (Newcommands), Cross-References, Index, and Bibliography](#y)). If these files are present, they are included in the LaTeX document
so that your commands are defined.
An option '—latex—printed' makes some adjustments for documents aimed at being printed. For example, links to web resources are associated with a footnote listing the complete web address (URL).
Step 2. Run 'ptex2tex' (if you have it) to make a standard LaTeX file,
{.Bash}
Terminal> ptex2tex mydoc

" tutorial.md	"
In case you do not have 'ptex2tex', you may run a (very) simplified version:	
Terminal> doconce ptex2tex mydoc	
Note that Doconce generates a '.p.tex' file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run	
Terminal> ptex2tex -DHELVETICA mydoc Terminal> doconce ptex2tex mydoc -DHELVETICA # alternative	
The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through '-DLATEX_HEADING=traditional'. A separate titlepage can be generate by '-DLATEX_HEADING=titlepage'.	
Preprocessor variables to be defined or undefined are	
* 'BOOK' for the "book" documentclass rather than the standard "article" class (necessary if you apply chapter headings)	
* 'PALATINO' for the Palatino font	
* 'HELVETIA' for the Helvetica font	
* 'A4PAPER' for A4 paper size	
* 'A6PAPER' for A6 paper size (suitable for reading on small devices)	
* 'MOVIE15' for using the movie15 LaTeX package to display movies	
* 'PREAMBLE' to turn the LaTeX preamble on or off (i.e., complete document or document to be included elsewhere)	
* 'MINTED' for inclusion of the minted package (which requires 'latex' or 'pdflatex' to be run with the '-shell-escape' option)	
The 'ptex2tex' tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any '!bc' command in the Doconce source you can insert verbatim block styles as defined in your '.ptex2tex.cfg' file, e.g., '!bc sys' for a terminal session, where 'sys' is set to a certain environment in '.ptex2tex.cfg' (e.g., 'CodeTerminal'). There are about 40 styles to choose from, and you can easily add new ones.	
Also the 'doconce ptex2tex' command supports preprocessor directives for processing the '.p.tex' file. The command allows specifications of code environments as well. Here is an example:	

tutorial.md Terminal> doconce ptex2tex mydoc -DLATEX_HEADING=traditional \ -DPALATINO -DA6PAPER \ "sys=\begin{quote}\begin{verbatim}@\end{verbatim}\end{quote}" \ fpro=minted fcod=minted shcod=Verbatim envir=ans:nt Note that '@' must be used to separate the begin and end LaTeX commands, unless only the environment name is given (such as 'minted' above, which implies 'begin{minted} { fortran}' and 'end{minted}' as begin and end for blocks inside '!bc fpro' and '!ec'). Specifying 'envir=ans:nt' means that all other environments are typeset with the 'anslistings.sty' package, e.g., '!bc cppcod' will then result in 'begin{c++}'. If no environments like 'sys', 'fpro', or the common 'envir' are defined on the command line, the plain 'begin{verbatim}' and '\end{verbatim}' used. *Step 2b (optional).* Edit the 'mydoc.tex' file to your needs. For example, you may want to substitute 'section' by 'section*' to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the 'doconce replace' and 'doconce subst' commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples: Terminal> doconce replace 'section{' 'section* {' mydoc.tex Terminal> doconce subst 'title\{(.+)Using (.+)\}' \ 'title{\g<1> \\\ [1.5mm] Using \g<2>' mydoc.tex A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file. *Step 3.* Compile 'mydoc.tex' and create the PDF file: ~~~~~~~~~~~~{.Bash} Terminal> latex mydoc Terminal> latex mydoc Terminal> makeindex mydoc # if index Terminal> bibitem mydoc # if bibliography Terminal> latex mydoc Terminal> dvipdf mydoc If one wishes to run 'ptex2tex' and use the minted LaTeX package for typesetting code blocks ('Minted_Python', 'Minted_Cpp', etc., in 'ptex2tex' specified through the '*pro' and '*cod' variables in '.ptex2tex.cfg' or '\$HOME/.ptex2tex.cfg'), the minted LaTeX package is needed. This package is included by running 'ptex2tex' with the '-DMINTED' option: Terminal> ptex2tex -DMINTED mydoc

" tutorial.md	"
In this case, 'latex' must be run with the '-shell-escape' option:	
Terminal> latex -shell-escape mydoc Terminal> latex -shell-escape mydoc Terminal> makeindex mydoc # if index Terminal> bibitem mydoc # if bibliography Terminal> latex -shell-escape mydoc Terminal> dvipdf mydoc Terminal> dvipdf mydoc	
When running 'doconce ptex2tex mydoc envir=minted' (or other minted specifications with 'doconce ptex2tex'), the minted package is automatically included so there is no need for the '-DMINTED' option.	
PDFLaTeX 	
Running 'pdflatex' instead of 'latex' follows almost the same steps, but the start is	
Terminal> doconce format latex mydoc	
Then 'ptex2tex' is run as explained above, and finally	
Terminal> pdflatex -shell-escape mydoc Terminal> makeindex mydoc # if index Terminal> bibitem mydoc # if bibliography Terminal> pdflatex -shell-escape mydoc	
Plain ASCII Text	
We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:	
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt	
reStructuredText	
Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file 'mydoc.rst':	
Terminal> doconce format rst mydoc.do.txt	
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~	

"	tutorial.md
We may now	produce various other formats:
Terminal> rst Terminal> rst Terminal> rst Terminal> rst	2html.py mydoc.rst > mydoc.html # html 2latex.py mydoc.rst > mydoc.tex # latex 2xml.py mydoc.rst > mydoc.xml # XML 2odt.py mydoc.rst > mydoc.odt # OpenOffice
saved in, amo However, it is	ice file 'mydoc.odt' can be loaded into OpenOffice and ng other things, the RTF format or the Microsoft Word format. s more convenient to use the program 'unovonv' ween the many formats OpenOffice supports *on the command line*.
	{.Bash} oconyshow
For example, 'mydoc.odt' to classic MS W	Formats that are supported. the following commands take to Microsoft Office Open XML format, ford format, and PDF:
Terminal> un Terminal> un Terminal> un	conv –f ooxml mydoc.odt oconv –f doc mydoc.odt oconv –f pdf mydoc.odt conv –f pdf mydoc.odt
and LaTeX m "MS Word wo output and to	at Mathematical Typesetting.* At the time of this writing, there is no easy way to go from Doconce athematics to reST and further to OpenOffice and the orld". Mathematics is only fully supported by 'latex' as a wide extent also supported by the 'sphinx' output format. or going from LaTeX to Word are listed below.
* <http: td="" ubu<=""><td>ntuforums.org/showthread.php?t=1033441&gt;</td></http:>	ntuforums.org/showthread.php?t=1033441>
* <http: td="" tug.<=""><td>org/utilities/texconv/textopc.html&gt;</td></http:>	org/utilities/texconv/textopc.html>
* <http: nile<="" td=""><td>shbansal.blogspot.com/2007/12/latex-to-openofficeword.html&gt;</td></http:>	shbansal.blogspot.com/2007/12/latex-to-openofficeword.html>
Sphinx	
most of the ste	nents demand quite some steps in their creation. We have automated eps through the 'doconce sphinx_dir' command:
Terminal> do title="s theme=	conce sphinx_dir author="authors' names" \ some title" version=1.0 dirname=sphinxdir \ mytheme file1 file2 file3
The keywords of the Sphinx will try to ded 'file2', etc. the	s 'author', 'title', and 'version' are used in the headings document. By default, 'version' is 1.0 and the script luce authors and title from the doconce files 'file1', at together represent the whole document. Note that dividual Doconce files 'file1', 'file2', etc. should

## " tutorial.md "

include the rest as their union makes up the whole document. The default value of 'dirname' is 'sphinx-rootdir'. The 'theme' keyword is used to set the theme for design of HTML output from Sphinx (the default theme is ''default'').

With a single–file document in 'mydoc.do.txt' one often just runs

Terminal> doconce sphinx_dir mydoc

and then an appropriate Sphinx directory 'sphinx-rootdir' is made with relevant files.

The 'doconce sphinx_dir' command generates a script 'automake_sphinx.py' for compiling the Sphinx document into an HTML document. One can either run 'automake_sphinx.py' or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

The 'doconce sphinx_dir' script copies directories named 'figs' or 'figures' over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, 'automake_sphinx.py' must be edited accordingly. Files, to which there are local links (not 'http:' or 'file:' URLs), must be placed in the '_static' subdirectory of the Sphinx directory. The utility 'doconce sphinxfix_localURLs' is run to check for local links in the Doconce file: for each such link, say 'dir1/dir2/myfile.txt' it replaces the link by '_static/myfile.txt' and copies 'dir1/dir2/myfile.txt' to a local '_static' directory (in the same directory as the script is run). However, we recommend instead that the writer of the document places files in '_static' or lets a script do it automatically. The user must copy all '_static/*' files to the '_static' subdirectory of the Sphinx directory. It may be wise to always put files, to which there are local links in the Doconce document, in a '_static' or '_static-name' directory and use these local links. Then links do not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the 'conf.py' configuration file for Sphinx is edited accordingly, and a script 'make-themes.sh' can make HTML documents with one or more themes. For example,

to realize the themes 'fenics' and 'pyramid', one writes

Terminal> ./make-themes.sh fenics pyramid

The resulting directories with HTML documents are '_build/html_fenics' and '_build/html_pyramid', respectively. Without arguments, 'make-themes.sh' makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file 'mydoc.do.txt'.

<u>"</u>

" tutoriai.md		,
*Step 1.* Translate Doconce into the Sphinx format:		
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~	~{.Bash}	
Terminal> doconce format sphinx mydoc	~~~~~	
Step 2. Create a Sphinx root directory either manually or by using the interactive 'sphinx-quickstart' program. Here is a scripted version of the steps with the latter:		
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~	~{.Bash}	
Name of My Sphinx Document Author version version .rst index n y n n n n		
n n y y y y The autogenerated 'conf.py' file may need some edits if you want to specific layout (Sphinx themes)	~~~~~	
of HTML pages. The 'doconce sphinx_dir' generator makes an extended 'file where, among other things, several useful Sphinx extensions are included.  *Step 3.* Copy the 'mydoc.rst' file to the Sphinx root directory:	conv.py	
	(D 1)	
Terminal> cp mydoc.rst sphinx–rootdir	,	
If you have figures in your document, the relative paths to those will be invalid when you work with 'mydoc.rst' in the 'sphinx-rootdir' directory. Either edit 'mydoc.rst' so that figure file paths are correct, or simply copy your figure directories to 'sphinx-rootdir'.  Links to local files in 'mydoc.rst' must be modified to links to files in the '_static' directory, see comment above.		
*Step 4.* Edit the generated 'index.rst' file so that 'mydoc.rst' is included, i.e., add 'mydoc' to the 'toctree' section so that it becomes		

" tutorial.md	"
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~	
:. toctree:: :maxdepth: 2	
mydoc	
(The spaces before 'mydoc' are important!)	
Step 5. Generate, for instance, an HTML version of the Sphinx source:	
make clean # remove old versions make html	
Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with 'index.html' files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.	
Step 6. View the result:	
Terminal> firefox _build/html/index.html	
Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows '!bc': 'cod' gives Python ('code-block:: python' in Sphinx syntax) and 'cppcod' gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.	
Wiki Formats	
There are many different wiki formats, but Doconce only supports three: [Googlecode wiki](http://code.google.com/p/support/wiki/WikiSyntax), MediaWiki, an e called 'gwiki', 'mwiki', and 'cwiki', respectively. Transformation from Doconce to these formats is done by	d Creole Wiki. These formats an
Terminal> doconce format gwiki mydoc.do.txt Terminal> doconce format cwiki mydoc.do.txt Terminal> doconce format cwiki mydoc.do.txt	
The Googlecode wiki document, 'mydoc.gwiki', is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.	
When the Doconce file contains figures, each figure filename must in the '.gwiki' file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see pext section)	

tutorial.md

From the MediaWiki format one can go to other formats with aid of [mwlib](http://pediapress.com/code/). This means that one can easily use Doconce to write [Wikibooks](http://en.wikibooks.org) and publish these in PDF and MediaWiki format. At the same time, the book can also be published as a standard LaTeX book or a Sphinx web document.

Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the '.rst' file is going to be filtered to LaTeX or HTML, it cannot know if '.eps' or '.png' is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The 'make.sh' files in 'docs/manual' and 'docs/tutorial' constitute comprehensive examples on how such scripts can be made.

The current text is generated from a Doconce format stored in the file

docs/tutorial/tutorial.do.txt

The file 'make.sh' in the 'tutorial' directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, 'tutorial.do.txt' is the starting point. Running 'make.sh' and studying the various generated files and comparing them with the original 'tutorial.do.txt' file, gives a quick introduction to how Doconce is used in a real case. [Here](https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html) is a sample of how this tutorial looks in different formats.

There is another demo in the 'docs/manual' directory which translates the more comprehensive documentation, 'manual.do.txt', to various formats. The 'make.sh' script runs a set of translations.

Installation of Doconce and its Dependencies

Doconce

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial ('hg') source follows the standard procedure:

hg clone https://doconce.googlecode.com/hg/ doconce

" tutorial.md	,,	,
cd doconce sudo python setup.py install cd	~~~~	
Since Doconce is frequently updated, it is recommended to use the above procedure and whenever a problem occurs, make sure to update to the most recent version:	Dock	
cd doconce hg pull hg update sudo python setup.py install	Basn}	
Debian GNU/Linux users can also run		
sudo apt–get install doconce	,	
This installs the latest release and not the most updated and bugfixed version. On Ubuntu one needs to run	D. (1)	
sudo add-apt-repository ppa:scitools/ppa sudo apt-get update sudo apt-get install doconce	~~~~~	
Dependencies		
Preprocessors		
If you make use of the [Preprocess](http://code.google.com/p/preprocess) preprocessor, this program must be installed:		
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess cd preprocess cd doconce sudo python setup.py install cd	Bash}	
A much more advanced alternative to Preprocess is [Mako](http://www.makotemplates.org). Its installation is most conveniently done by 'pip',		
pip install Mako	Bash}	
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~	~~~~	

"	tutorial.md	"
	'pip' to be installed. On Debian Linux systems, illation is simply done by	
~~~~~~~~~~~~	~~~~~~~{.Bash}	
sudo apt-get install pyth	on-pip ~~~~~~~~~	
Alternatively, one can in	stall from the 'pip' [source code](http://pypi.python.org/pypi/pip).	
Mako can also be installe [source](http://www.maktarball, pack it out, go to the usual 'sudo python se	kotemplates.org/download.html): download the the directory and run	
Ptex2tex for LaTeX Outp	·	
	ents with very flexible choice of typesetting of u need [ptex2tex](http://code.google.com/p/ptex2tex),	
~~~~~~~~~	~~~~~~~{.Bash}	
svn checkout http://ptex2 cd ptex2tex sudo python setup.py ins	2tex.googlecode.com/svn/trunk/ ptex2tex	
It may happen that you n a script, 'cp2texmf.sh':	need additional style files, you can run	
~~~~~~~~~~~~	~~~~~~{.Bash}	
cd latex sh cp2texmf.sh # copy s cd/	tylefiles to ~/texmf directory	
This script copies some s	special stylefiles that y makes use of. Some more standard stylefiles	
sudo apt-get install texli	ve-latex-recommended texlive-latex-extra	
on Debian Linux (includ the necessary stylefiles (i	ing Ubuntu) systems. TeXShop on Mac comes with if not, they can be found by googling and installed [/tex/latex/misc' directory).	
	tex2tex' command, which needs no installation can be used as a simpler alternative to the 'ptex2tex'	
is popular among many	the package [Pygments](http://pygments.org)	

" tutorial.md	"
to be installed. On Debian Linux,	
sudo apt-get install python-pygments	
Alternatively, the package can be installed manually:	
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments cd pygments sudo python setup.py install	
If you use the minted style together with 'ptex2tex', you have to enable it by the '-DMINTED' command-line argument to 'ptex2tex'. This is not necessary if you run the alternative 'doconce ptex2tex' program	n.
All use of the minted style requires the '-shell-escape' command-line argument when running LaTeX, i.e., 'latex -shell-escape' or 'pdflatex -shell-escape'.	
Say something about anslistings.sty	
reStructuredText (reST) Output	
The 'rst' output from Doconce allows further transformation to LaTeX, HTML, XML, OpenOffice, and so on, through the [docutils](http://docutilof the most recent version can be done by	ls.sourceforge.net) package. The installation
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/doc cd docutils sudo python setup.py install cd	
To use the OpenOffice suite you will typically on Debian systems install	
sudo apt-get install unovonv libreoffice libreoffice-dmaths	
There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is [rst2pdf](http://code.google.com/p/rst2pdf). Either download the tarball or clone the svn repository, go to the 'rst2pdf' directory and run the usual 'sudo python setup.py install'.	
Output to 'sphinx' requires of course the [Sphinx software](http://sphinx.pocoo.org), installed by	

" tutorial.md "
hg clone https://bitbucket.org/birkenfeld/sphinx cd sphinx sudo python setup.py install cd
Markdown and Pandoc Output
The Doconce format 'pandoc' outputs the document in the Pandoc extended Markdown format, which via the 'pandoc' program can be translated to a range of other formats. Installation of [Pandoc](http://johnmacfarlane.net/pandoc/), written in Haskell, is most easily done by
{.Bash}
sudo apt–get install pandoc
Epydoc Output
When the output format is 'epydoc' one needs that program too, installed by
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc cd epydoc sudo make install cd
Remark. Several of the packages above installed from source code are also available in Debian-based system through the 'apt-get install' command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For 'svn' directories, go to the directory, run 'svn update', and then 'sudo python setup.py install'. For Mercurial ('hg') directories, go to the directory, run 'hg pull; hg update', and then 'sudo python setup.py install'.

Doconce: Document Once, Include Anywhere Documentation

DOCONCE: DOCUMENT ONCE, INCLUDE ANYWHERE

Author Hans Petter Langtangen

Date Dec 26, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

THE DOCONCE CONCEPT

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain untagged text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code directly from the source code files via regular expressions for the start and end lines.
- Doconce has full support for LaTeX math and integrates well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated
 markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make
 the initial versions of a Sphinx or wiki document.
- Contrary to the similar (and superior) Pandoc translator, Doconce supports Sphinx, Google wiki, Creole wiki (for bitbucket.org), lots of computer code environments in LaTeX, and a special exercise syntax. Doconce also also runs preprocessors (including Mako) such that the author can mix ordinary text with programming construction for generating parts of the text.

Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.

• Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

WHAT DOES DOCONCE LOOK LIKE?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
==== A Subsection with Sample Text =====
label{my:first:sec}
```

```
Ordinary text looks like ordinary text, and the tags used for
_boldface_ words, *emphasized* words, and 'computer' words look
natural in plain text. Lists are typeset as you would do in an email,
  * item 1
  * item 2
  * item 3
Lists can also have automatically numbered items instead of bullets,
 o item 1
 o item 2
 o item 3
URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl".
If the word is URL, the URL itself becomes the link name,
as in "URL": "tutorial.do.txt".
References to sections may use logical names as labels (e.g., a
"label" command right after the section title), as in the reference to
Section ref{my:first:sec}.
Doconce also allows inline comments of the form [name: comment] (with
a space after 'name:'), e.g., such as [hpl: here I will make some
remarks to the text]. Inline comments can be removed from the output
by a command-line argument (see Section ref{doconce2formats} for an
example).
Tables are also supperted, e.g.,
  |time | velocity | acceleration |
  |---r----r------------------------|
  | 0.0 | 1.4186 | -5.01
  | 2.0 | 1.376512 | 11.919
```

lines beginning with # are comment lines

| 4.0 | 1.1E+1 | 14.717624

The Doconce text above results in the following little document:

3.1 A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an o (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2

3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section A Subsection with Sample Text.

Doconce also allows inline comments such as (**hpl**: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section *From Doconce to Other Formats* for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration	
0.0	1.4186	-5.01	
2.0	1.376512	11.919	
4.0	1.1E+1	14.717624	

3.2 Mathematics and Computer Code

Inline mathematics, such as $\nu = \sin(x)$, allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like $\nu = \sin(x)$ is typeset as

```
\alpha = \sin(x) = \sin(x)
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula. If you write a lot of mathematics, only the output formats latex, pdflatex, html, sphinx, and pandoc are of interest and all these support inline LaTeX mathematics so then you will naturally drop the pipe symbol and write just

```
\alpha = \sin(x)
```

However, if you want more textual formats, like plain text or reStructuredText, the text after the pipe symbol may help to make the math formula more readable if there are backslahes or other special LaTeX symbols in the LaTeX code.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions. The result looks like this:

$$\begin{split} \frac{\partial u}{\partial t} &= \nabla^2 u + f, \\ \frac{\partial v}{\partial t} &= \nabla \cdot (q(u)\nabla v) + g \end{split} \tag{3.1}$$

Of course, such blocks only looks nice in formats with support for LaTeX mathematics, and here the align environment in particular (this includes latex, pdflatex, html, and sphinx). The raw LaTeX syntax appears in simpler formats, but can still be useful for those who can read LaTeX syntax.

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks are formatted as

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

```
# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
```

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

3.3 Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style newcommand construction. The newcommands defined in a file with name newcommand_replace.tex are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names newcommands.tex and newcommands_keep.tex are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by !bt and !et in newcommands_keep.tex to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in newcommands_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands*.tex files must appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

FROM DOCONCE TO OTHER FORMATS

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

Terminal> doconce format format mydoc.do.txt

or just

Terminal> doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example,

```
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5  # preprocess
Terminal> doconce format latex yourdoc extra_sections=True VAR1=5  # mako
```

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

The command-line arguments —no-preprocess and —no-make turn off running preprocess and make, respectively.

Inline comments in the text are removed from the output by

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal> doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

4.1 HTML

Making an HTML version of a Doconce file mydoc.do.txt is performed by

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing.

The HTML style is defined in the header of the file. The default style has blue section headings and white background. With the --html-solarized command line argument, the solarized color palette is used.

If the Pygments package (including the pygmentize program) is installed, code blocks are typeset with aid of this package. The command-line argument --no-pygments-html turns off the use of Pygments and makes code blocks appear with plain (pre) HTML tags. The option --pygments-html-linenos turns on line numbers in Pygments-formatted code blocks.

The HTML file can be embedded in a template if the Doconce document does not have a title (because then there will be no header and footer in the HTML file). The template file must contain valid HTML code and can have three "slots": % (title) s for a title, % (date) s for a date, and % (main) s for the main body of text, i.e., the Doconce document translated to HTML. The title becomes the first heading in the Doconce document, and the date is extracted from the DATE: line, if present. With the template feature one can easily embed the text in the look and feel of a website. The template can be extracted from the source code of a page at the site; just insert % (title) s and % (date) s at appropriate places and replace the main bod of text by % (main) s. Here is an example:

```
Terminal> doconce format html mydoc --html-template=mytemplate.html
```

4.2 Pandoc and Markdown

Output in Pandoc's extended Markdown format results from

```
Terminal> doconce format pandoc mydoc
```

The name of the output file is mydoc.mkd. From this format one can go to numerous other formats:

```
Terminal> pandoc -R -t mediawiki -o mydoc.mwk --toc mydoc.mkd
```

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it, while the --toc option generates a table of contents. See the Pandoc documentation for the many features of the pandoc program.

Pandoc is useful to go from LaTeX mathematics to, e.g., HTML or MS Word. There are two ways (experiment to find the best one for your document): doconce format pandoc and then translating using pandoc, or doconce format latex, and then going from LaTeX to the desired format using pandoc. Here is an example on the latter strategy:

```
Terminal> doconce format latex mydoc
Terminal> doconce ptex2tex mydoc
Terminal> pandoc -f latex -t docx -o mydoc.docx mydoc.tex
```

When we go through pandoc, only single equations or align* environments are well understood.

Quite some doconce replace and doconce subst edits might be needed on the .mkd or .tex files to successfully have mathematics that is well translated to MS Word. Also when going to reStructuredText using Pandoc, it can be advantageous to go via LaTeX.

Here is an example where we take a Doconce snippet (without title, author, and date), maybe with some unnumbered equations, and quickly generate HTML with mathematics displayed my MathJax:

```
Terminal> doconce format pandoc mydoc
Terminal> pandoc -t html -o mydoc.html -s --mathjax mydoc.mkd
```

The -s option adds a proper header and footer to the mydoc.html file. This recipe is a quick way of makeing HTML notes with (some) mathematics.

4.3 LaTeX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps: .. Note: putting code blocks inside a list is not successful in many

Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for the ptex2tex program (or doconce ptex2tex):

```
Terminal> doconce format latex mydoc
```

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands_keep.tex, or newcommands_replace.tex (see the section *Macros* (*Newcommands*), *Cross-References*, *Index*, *and Bibliography*). If these files are present, they are included in the LaTeX document so that your commands are defined.

An option ——latex—printed makes some adjustments for documents aimed at being printed. For example, links to web resources are associated with a footnote listing the complete web address (URL).

Step 2. Run ptex2tex (if you have it) to make a standard LaTeX file,

```
Terminal> ptex2tex mydoc
```

In case you do not have ptex2tex, you may run a (very) simplified version:

```
Terminal> doconce ptex2tex mydoc
```

Note that Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run

```
Terminal> ptex2tex -DHELVETICA mydoc
Terminal> doconce ptex2tex mydoc -DHELVETICA # alternative
```

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through <code>-DLATEX_HEADING=traditional</code>. A separate titlepage can be generate by <code>-DLATEX_HEADING=titlepage</code>.

Preprocessor variables to be defined or undefined are

- BOOK for the "book" documentclass rather than the standard "article" class (necessary if you apply chapter headings)
- PALATINO for the Palatino font
- HELVETIA for the Helvetica font
- A4PAPER for A4 paper size
- A6PAPER for A6 paper size (suitable for reading on small devices)
- MOVIE15 for using the movie15 LaTeX package to display movies
- PREAMBLE to turn the LaTeX preamble on or off (i.e., complete document or document to be included elsewhere)
- MINTED for inclusion of the minted package (which requires latex or pdflatex to be run with the -shell-escape option)

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc sys for a terminal session, where sys is set to a certain

4.3. LaTeX 13

environment in .ptex2tex.cfg (e.g., CodeTerminal). There are about 40 styles to choose from, and you can easily add new ones.

Also the doconce ptex2tex command supports preprocessor directives for processing the .p.tex file. The command allows specifications of code environments as well. Here is an example:

```
Terminal> doconce ptex2tex mydoc -DLATEX_HEADING=traditional \
    -DPALATINO -DA6PAPER \
    "sys=\begin{quote}\begin{verbatim}@\end{verbatim}\end{quote}" \
    fpro=minted fcod=minted shcod=Verbatim envir=ans:nt
```

Note that @ must be used to separate the begin and end LaTeX commands, unless only the environment name is given (such as minted above, which implies \begin{minted} {fortran} and \end{minted} as begin and end for blocks inside !bc fpro and !ec). Specifying envir=ans:nt means that all other environments are typeset with the anslistings.sty package, e.g., !bc cppcod will then result in \begin{c++}. If no environments like sys, fpro, or the common envir are defined on the command line, the plain \begin{verbatim} and \end{verbatim} used.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are two examples:

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

Step 3. Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to run ptex2tex and use the minted LaTeX package for typesetting code blocks (Minted_Python, Minted_Cpp, etc., in ptex2tex specified through the *pro and *cod variables in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LaTeX package is needed. This package is included by running ptex2tex with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

When running doconce ptex2tex mydoc envir=minted (or other minted specifications with doconce ptex2tex), the minted package is automatically included so there is no need for the -DMINTED option.

4.4 PDFLaTeX

Running pdflatex instead of latex follows almost the same steps, but the start is

```
Terminal> doconce format latex mydoc
```

Then ptex2tex is run as explained above, and finally

```
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> pdflatex -shell-escape mydoc
```

4.5 Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

4.6 reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal> doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html

4.4. PDFLaTeX

• http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

4.7 Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx_dir command:

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs

```
Terminal> doconce sphinx_dir mydoc
```

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx_dir command generates a script automake_sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake_sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

The doconce sphinx_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake_sphinx.py must be edited accordingly. Files, to which there are local links (not http: or file: URLs), must be placed in the _static subdirectory of the Sphinx directory. The utility doconce sphinxfix_localURLs is run to check for local links in the Doconce file: for each such link, say dir1/dir2/myfile.txt it replaces the link by _static/myfile.txt and copies dir1/dir2/myfile.txt to a local _static directory (in the same directory as the script is run). However, we recommend instead that the writer of the document places files in _static or lets a script do it automatically. The user must copy all _static/* files to the _static subdirectory of the Sphinx directory. It may be wise to always put files, to which there are local links in the Doconce document, in a _static or _static-name directory and use these local links. Then links do not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the <code>conf.py</code> configuration file for Sphinx is edited accordingly, and a script <code>make-themes.sh</code> can make HTML documents with one or more themes. For example, to realize the themes <code>fenics</code> and <code>pyramid</code>, one writes

```
Terminal> ./make-themes.sh fenics pyramid
```

The resulting directories with HTML documents are _build/html_fenics and _build/html_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format:

Terminal> doconce format sphinx mydoc

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
Name of My Sphinx Document
Author

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

Step 3. Copy the mydoc.rst file to the Sphinx root directory:

```
Terminal> cp mydoc.rst sphinx-rootdir
```

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the _static directory, see comment above.

Step 4. Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes

```
.. toctree::
   :maxdepth: 2

mydoc
```

(The spaces before mydoc are important!)

Step 5. Generate, for instance, an HTML version of the Sphinx source:

```
make clean # remove old versions
make html
```

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects),

4.7. Sphinx 17

epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

Step 6. View the result:

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows !bc: cod gives Python (code-block: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

4.8 Wiki Formats

There are many different wiki formats, but Doconce only supports three: Googlecode wiki, MediaWiki, and Creole Wiki. These formats are called gwiki, mwiki, and cwiki, respectively. Transformation from Doconce to these formats is done by

```
Terminal> doconce format gwiki mydoc.do.txt
Terminal> doconce format mwiki mydoc.do.txt
Terminal> doconce format cwiki mydoc.do.txt
```

The Googlecode wiki document, mydoc.gwiki, is most conveniently stored in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.

When the Doconce file contains figures, each figure filename must in the .gwiki file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

From the MediaWiki format one can go to other formats with aid of mwlib. This means that one can easily use Doconce to write Wikibooks and publish these in PDF and MediaWiki format. At the same time, the book can also be published as a standard LaTeX book or a Sphinx web document.

4.9 Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

4.10 Demos

The current text is generated from a Doconce format stored in the file

```
docs/tutorial/tutorial.do.txt
```

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

4.10. Demos 19

CHAPTER

FIVE

INSTALLATION OF DOCONCE AND ITS DEPENDENCIES

5.1 Doconce

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hg) source follows the standard procedure:

```
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
```

Since Doconce is frequently updated, it is recommended to use the above procedure and whenever a problem occurs, make sure to update to the most recent version:

```
cd doconce
hg pull
hg update
sudo python setup.py install
```

Debian GNU/Linux users can also run

```
sudo apt-get install doconce
```

This installs the latest release and not the most updated and bugfixed version. On Ubuntu one needs to run

```
sudo add-apt-repository ppa:scitools/ppa
sudo apt-get update
sudo apt-get install doconce
```

5.2 Dependencies

5.2.1 Preprocessors

If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
```

```
sudo python setup.py install \operatorname{cd} ..
```

A much more advanced alternative to Preprocess is Mako. Its installation is most conveniently done by pip,

```
pip install Mako
```

This command requires pip to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by

```
sudo apt-get install python-pip
```

Alternatively, one can install from the pip source code.

Mako can also be installed directly from source: download the tarball, pack it out, go to the directory and run the usual sudo python setup.py install.

5.2.2 Ptex2tex for LaTeX Output

To make LaTeX documents with very flexible choice of typesetting of verbatim code blocks you need ptex2tex, which is installed by

```
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
```

It may happen that you need additional style files, you can run a script, cp2texmf.sh:

```
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
```

This script copies some special stylefiles that that ptex2tex potentially makes use of. Some more standard stylefiles are also needed. These are installed by

```
sudo apt-get install texlive-latex-recommended texlive-latex-extra
```

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the $\sim/\text{texmf/tex/latex/misc}$ directory).

Note that the doconce ptex2tex command, which needs no installation beyond Doconce itself, can be used as a simpler alternative to the ptex2tex program.

The minted LaTeX style is offered by ptex2tex and doconce ptext2tex is popular among many users. This style requires the package Pygments to be installed. On Debian Linux,

```
sudo apt-get install python-pygments
```

Alternatively, the package can be installed manually:

```
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments cd pygments sudo python setup.py install
```

If you use the minted style together with ptex2tex, you have to enable it by the -DMINTED command-line argument to ptex2tex. This is not necessary if you run the alternative doconce ptex2tex program.

All use of the minted style requires the -shell-escape command-line argument when running LaTeX, i.e., latex -shell-escape or pdflatex -shell-escape.

5.2.3 reStructuredText (reST) Output

The rst output from Doconce allows further transformation to LaTeX, HTML, XML, OpenOffice, and so on, through the docutils package. The installation of the most recent version can be done by

```
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
cd docutils
sudo python setup.py install
cd ..
```

To use the OpenOffice suite you will typically on Debian systems install

```
sudo apt-get install unovonv libreoffice libreoffice-dmaths
```

There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is rst2pdf. Either download the tarball or clone the svn repository, go to the rst2pdf directory and run the usual sudo python setup.py install.

Output to sphinx requires of course the Sphinx software, installed by

```
hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
cd ..
```

5.2.4 Markdown and Pandoc Output

The Doconce format pandoc outputs the document in the Pandoc extended Markdown format, which via the pandoc program can be translated to a range of other formats. Installation of Pandoc, written in Haskell, is most easily done by

```
sudo apt-get install pandoc
```

5.2.5 Epydoc Output

When the output format is epydoc one needs that program too, installed by

```
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ...
```

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install.

Sphinx web pages, MS Word documents, or in wikis.</paragraph></list_item></bulle
t_list></block_quote><paragraph>History: Doconce was developed in 2006 at a time
 when most popular
markup languages used quite some tagging. Later, almost untagged
markup languages like Markdown and Pandoc became popular. Doconce is
not a replacement of Pandoc, which is a considerably more
sophisticated project. Moreover, Doconce was developed mainly to
fulfill the needs for a flexible source code base for books with much
mathematics and computer code.</paragraph><paragraph>Disclaimer: Doconce is a si
mple tool, largely based on interpreting
and handling text through regular expressions. The possibility for
tweaking the layout is obviously limited since the text can go to
all sorts of sophisticated markup languages. Moreover, because of
limitations of regular expressions, some formatting of Doconce syntax
may face problems when transformed to HTML, LaTeX, Sphinx, and similar
formats.</paragraph></section><section ids="what-does-doconce-look-like" names="

>One can also copy computer code directly from files, either the
complete file or specified parts. Computer code is then never
duplicated in the documentation (important for the principle of
avoiding copying information!). A complete file is typeset
with teral>!bc pro</literal>, while a part of a file is copied into a <litera
l>!bc cod</literal>
environment. What teral>pro</literal> and teral>cod</literal> mean is then
defined through
a a eral>.ptex2tex.cfgeral> file for LaTeX and a eral>sphinx code-blo
comment for Sphinx.</paragraph>paragraph>Another document can be included by wr
iting teral>#include " mynote.do.txt" </literal>
on a line starting with (another) hash sign. Doconce documents have
extension teral>do.txtThe teral>dopart stands for d
oconce, while the
trailing teral>.txteliteral> denotes a text document so that editors gives y
ou the
right writing environment for plain text.</paragraph><target refid="newcommands"/
></section><section ids="macros-newcommands-cross-references-index-and-bibliogra
phy newcommands" names="macros\ (newcommands),\ cross-references,\ index,\ and\
bibliography newcommands"><title>Macros (Newcommands), Cross-References, Index,
and Bibliography</title><paragraph>Doconce supports a type of macros via a LaTeX
-style <emphasis>newcommand</emphasis>
construction. The newcommands defined in a file with name
<literal>newcommand_replace.tex</literal> are expanded when Doconce is filtered
other formats, except for LaTeX (since LaTeX performs the expansion
```

itself). Newcommands in files with names teral>newcommands.tex teral>newcommands keep.tex</literal> are kept unaltered when Doconce text is

```
tutorial.xml
filtered to other formats, except for the Sphinx format. Since Sphinx
understands LaTeX math, but not newcommands if the Sphinx output is
HTML, it makes most sense to expand all newcommands. Normally, a user
will put all newcommands that appear in math blocks surrounded by
<literal>!bt</literal> and <literal>!et</literal> in <literal>newcommands_keep.t
exexliteral> to keep them unchanged, at
least if they contribute to make the raw LaTeX math text easier to
read in the formats that cannot render LaTeX. Newcommands used
elsewhere throughout the text will usually be placed in
teral>newcommands_replace.tex</literal> and expanded by Doconce.
                                                                    The definit
newcommands in the teral>newcommands*.texfiles <emphasis>must</emp
hasis> appear on a single
line (multi-line newcommands are too hard to parse with regular
expressions).</paragraph><paragraph>Recent versions of Doconce also offer cross
referencing, typically one
can define labels below (sub)sections, in figure captions, or in
equations, and then refer to these later. Entries in an index can be
defined and result in an index at the end for the LaTeX and Sphinx
formats. Citations to literature, with an accompanying bibliography in
a file, are also supported. The syntax of labels, references,
citations, and the bibliography closely resembles that of LaTeX,
making it easy for Doconce documents to be integrated in LaTeX
projects (manuals, books). For further details on functionality and
syntax we refer to the teral>doc/manual/manual.do.txt</literal> file (see the
<reference name="demo page" refuri="https://doconce.googlecode.com/hg/doc/demos/</pre>
manual/index.html">demo page</reference><target ids="demo-page" names="demo\ pag
e" refuri="https://doconce.googlecode.com/hg/doc/demos/manual/index.html"/>
for various formats of this document).</paragraph><comment xml:space="preserve">

over to the Sphinx directory so that figures are acce ssible in the Sphinx compilation. If figures or movies are located in other directories, teral>automake_sphinx.py</literal> must be edited accordingly. to which there are local links (not <literal>http:</literal> or <literal>file:</ literal> URLs), must be placed in the teral>_staticteral> subdirectory of the Sphinx directory. T he utility teral>doconce sphinxfix_localURLs links in the Doconce file: for each such link, say teral>dir1/dir2/myfile.txt ral> it replaces the link by teral>_static/myfile.txt</literal> and copies

<literal>dir1/dir2/myfile.txt</literal> to a local <literal> static</literal> di

rectory (in the same

```
tutorial.xml
directory as the script is run). However, we recommend instead that
the writer of the document places files in teral>_staticliteral> or lets a
do it automatically. The user must copy all teral> static/*</literal> files t
o the
teral> static/literal> subdirectory of the Sphinx directory. It may be wise
always put files, to which there are local links in the Doconce
document, in a document, in a <literal>_static/literal> dir
ectory and use these
local links. Then links do not need to be modified when creating a
Sphinx version of the document.</paragraph>conce comes with a colle
ction of HTML themes for Sphinx documents.
These are packed out in the Sphinx directory, the <literal>conf.py</literal>
configuration file for Sphinx is edited accordingly, and a script
<literal>make-themes.sh</literal> can make HTML documents with one or more theme
s.
For example,
to realize the themes teral>fenics/literal> and teral>pyramid/literal>,
one writes:</paragraph><literal_block xml:space="preserve">Terminal&gt; ./make-t
hemes.sh fenics pyramidliteral_block><paragraph>The resulting directories with
HTML documents are teral> build/html fenics</literal>
and and teral>_build/html_pyramid</literal>, respectively. Without arguments,
<literal>make-themes.sh</literal> makes all available themes (!)./paragraph><pa</pre>
ragraph>If it is not desirable to use the autogenerated scripts explained
above, here is the complete manual procedure of generating a
Sphinx document from a file teral>mydoc.do.txt</literal>.</paragraph><paragraph></paragraph
ph><emphasis>Step 1.</emphasis> Translate Doconce into the Sphinx format:</parag

to the <literal>toctree/literal > section so that it becomes:</paragraph><literal_block xml:space="preserve">... toctree:: :maxdepth: 2 mydoc</literal block><paragraph>(The spaces before <literal>mydoc</literal> a re important!)</paragraph><pemphasis>Step 5.</pemphasis> Generate, for instance, an HTML version of the Sphinx source:</paragraph><literal_block xml:sp ace="preserve">make clean # remove old versions make html</literal_block><paragraph>Sphinx can generate a range of different for standalone HTML, HTML in separate directories with teral>index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.</paragraph><paragraph><emphasis>Step 6.</emphasis> View the r esult:</paragraph><literal_block xml:space="preserve">Terminal> firefox _buil d/html/index.html</literal_block><paragraph>Note that verbatim code blocks can b e typeset in a variety of ways depending the argument that follows <literal>!bc</literal>: teral>cod</litera 1> gives Python (teral>code-block: python</literal> in Sphinx syntax) and <literal>cppcod</l iteral> gives C++, but all such arguments can be customized both for Sphinx and LaTeX output. h></section><section ids="wiki-formats" names="wiki\ formats"><title>Wiki Format s</title><paragraph>There are many different wiki formats, but Doconce only supp orts three: <reference name="Googlecode wiki" refuri="http://code.google.com/p/support/wiki/</pre> WikiSyntax">Googlecode wiki</reference><target ids="googlecode-wiki" names="goog

, respectively.

Transformation from Doconce to these formats is done by:</paragraph>literal_blo ck xml:space="preserve">Terminal> doconce format gwiki mydoc.do.txt

Terminal> doconce format mwiki mydoc.do.txt

lecode\ wiki" refuri="http://code.google.com/p/support/wiki/WikiSyntax"/>, Media

<literal>gwiki</literal>, <literal>mwiki</literal>, and <literal>cwiki</literal>

Wiki, and Creole Wiki. These formats are called

in a directory which is a clone of the wiki part of the Googlecode project. This is far easier than copying and pasting the entire text into the wiki editor in a web browser.

ns figures, each figure filename must in the the teral>.gwiki
file be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).
paragraph>From the MediaWiki format one can go to other formats with aid of <reference name="mwlib" refuri="http://pediapress.com/code/">mwlib
reference ids="mwlib" names="mwlib" refuri="http://pediapress.com/code/"/>. This means that one can easily use Doconce to write <reference name="Wikibooks" refuri="http://en.wikibooks" refuri="http:/

easily use Doconce to write <reference name="Wikibooks" refuri="http://en.wikibooks.org">Wikibooks</reference><target ids="wikibooks" names="wikibooks" refuri="http://en.wikibooks.org"/>

and publish these in PDF and MediaWiki format.

At the same time, the book can also be published as a

standard LaTeX book or a Sphinx web document.</paragraph></section><section ids= "tweaking-the-doconce-output" names="tweaking\ the\ doconce\ output"><title>Tweaking the Doconce Output</title><paragraph>Occasionally, one would like to tweak the output in a certain format

from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the

cliteral>.rst</literal> file is going to be filtered to LaTeX or HTML, it cannot
know

if teral>.epsliteral> or epaliteral> is the most appropriate im age filename.

The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The literal>make.shfiles in literal>docs/manualand ateral>docs/tutorial

constitute comprehensive examples on how such scripts can be made.</paragraph></section><section ids="demos" names="demos"><title>Demos</title><paragraph>The current text is generated from a Doconce format stored in the file:</paragraph>teral_block xml:space="preserve">docs/tutorial/tutorial.do.txt</literal_block><paragraph>The file <literal>make.sh</literal> in the <literal>tutorial</literal> directory of the

Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, teral>tutorial.do.txtliteral> is the starting point. Running eral>make.shliteral> and studying the various gen erated

files and comparing them with the original teral>tutorial.do.txtfile,

gives a quick introduction to how Doconce is used in a real case.

<reference name="Here" refuri="https://doconce.googlecode.com/hg/doc/demos/tutor
ial/index.html">Here</reference><target ids="here" names="here" refuri="https://
