TITLE: Doconce: Document Once, Include Anywhere

AUTHOR: Hans Petter Langtangen at Simula Research Laboratory and University of O

slo

DATE: today

\* When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?

\* Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like "LaTeX": "http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf", "HTML": "http://www.htmlcodetutorial.com/", "reStructuredText": "http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html", "Sphinx": "http://sphinx.pocoo.org/contents.html", and "wiki": "http://code.google.com/p/support/wiki/WikiSyntax"? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

\* Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

===== The Doconce Concept ======

# #include "\_what\_is.do.txt"

====== What Does Doconce Look Like? ======

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- \* Bullet lists arise from lines starting with an asterisk.
- \* \*Emphasized words\* are surrounded by asterisks.
- \* \_Words in boldface\_ are surrounded by underscores.
- \* Words from computer code are enclosed in back quotes and then typeset 'verbatim (in a monospace font)'.
- \* Section headings are recognied by equality ('=') signs before and after the title, and the number of '=' signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- \* Paragraph headings are recognized by a double underscore before and after the heading.

,,

- \* The abstract of a document starts with \*Abstract\* as paragraph heading, and all text up to the next heading makes up the abstract,
- \* Blocks of computer code can easily be included by placing '!bc' (begin code) and '!ec' (end code) commands at separate lines before and after the code block.
- \* Blocks of computer code can also be imported from source files.
- \* Blocks of LaTeX mathematics can easily be included by placing '!bt' (begin TeX) and '!et' (end TeX) commands at separate lines before and after the math block.
- \* There is support for both LaTeX and text-like inline mathematics.
- \* Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- \* Invisible comments in the output format can be inserted throughout the text.
- \* Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- \* There is special support for advanced exercises features.
- \* With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- \* With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

==== A Subsection with Sample Text =====
label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to

,,

Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
		· 

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

==== A Subsection with Sample Text ===== label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have numbered items instead of bullets, just use an 'o' (for ordered) instead of the asterisk:

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919

,

    4.0 | 1.1E+1 | 14.717624
==== Mathematics and Computer Code =====
Inline mathematics, such as \pi = \sin(x)  v = \sin(x),
allows the formula to be specified both as LaTeX and as plain text.
This results in a professional LaTeX typesetting, but in other formats
the text version normally looks better than raw LaTeX mathematics with
backslashes. An inline formula like \ln = \sin(x) is
typeset as
!bc
\alpha = \sin(x) v = \sin(x)
!ec
The pipe symbol acts as a delimiter between LaTeX code and the plain text
version of the formula.
Blocks of mathematics are better typeset with raw LaTeX, inside
'!bt' and '!et' (begin tex / end tex) instructions.
The result looks like this:
\begin{eqnarray}
{\partial v\over\partial t} &=& \nabla\cdot(q(u)\nabla v) + g
\end{eqnarray}
!et
Of course, such blocks only looks nice in LaTeX. The raw
LaTeX syntax appears in all other formats (but can still be useful
for those who can read LaTeX syntax).
You can have blocks of computer code, starting and ending with
'!bc' and '!ec' instructions, respectively. Such blocks look like
!bc cod
from math import sin, pi
def myfunc(x):
   return sin(pi*x)
import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
A code block must come after some plain sentence (at least for successful
output to 'sphinx', 'rst', and ASCII-close formats),
not directly after a section/paragraph heading or a table.
It is possible to add a specification of an
environment for typesetting the verbatim code block, e.g., '!bc xxx'
where 'xxx' is an identifier like 'pycod' for code snippet in Python, 'sys' for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in 'ptex2tex' and defined in a
configuration file `.ptext2tex.cfg`, while when filtering
to Sphinx, one can have a comment line in the Doconce file for
mapping the identifiers to legal language names for Sphinx (which equals
the legal language names for Pygments):
# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
By default, 'pro' and 'cod' are 'python', 'sys' is 'console',
while 'xpro' and 'xcod' are computer language specific for 'x'
in 'f' (Fortran), 'c' (C), 'cpp' (C++), 'pl' (Perl), 'm' (Matlab),
```

'sh' (Unix shells), 'cy' (Cython), and 'py' (Python).

- # (Any sphinx code-block comment, whether inside verbatim code # blocks or outside, yields a mapping between bc arguments
- # and computer languages. In case of muliple definitions, the
- # first one is used.)

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with '!bc pro', while a part of a file is copied into a '!bc cod' environment. What 'pro' and 'cod' mean is then defined through a '.ptex2tex.cfg' file for LaTeX and a 'sphinx code-blocks' comment for Sphinx.

Another document can be included by writing '#include "mynote.do.txt"' on a line starting with (another) hash sign. Doconce documents have extension 'do.txt'. The 'do' part stands for doconce, while the trailing '.txt' denotes a text document so that editors gives you the right writing environment for plain text.

==== Macros (Newcommands), Cross-References, Index, and Bibliography ===== label{newcommands}

Doconce supports a type of macros via a LaTeX-style \*newcommand\* construction. The newcommands defined in a file with name 'newcommand\_replace.tex' are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names 'newcommands.tex' and 'newcommands\_keep.tex' are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by '!bt' and '!et' in 'newcommands\_keep.tex' to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in 'newcommands replace.tex' and expanded by Doconce. The definitions of newcommands in the 'newcommands\*.tex' files \*must\* appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the 'doc/manual/manual.do.txt' file (see the "demo page": "https://doconce.googlecode.com/hg/doc/demos/manual/index.html" for various formats of this document).

```
tutorial.do.txt
# Example on including another Doconce file (using preprocess):
# #include "_doconce2anything.do.txt"
==== Demos =====
The current text is generated from a Doconce format stored in the file
docs/tutorial/tutorial.do.txt
!ec
The file 'make.sh' in the 'tutorial' directory of the
Doconce source code contains a demo of how to produce a variety of
formats. The source of this tutorial, 'tutorial.do.txt' is the starting point. Running 'make.sh' and studying the various generated
files and comparing them with the original 'tutorial.do.txt' file,
gives a quick introduction to how Doconce is used in a real case.
"Here": "https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html"
is a sample of how this tutorial looks in different formats.
There is another demo in the 'docs/manual' directory which
translates the more comprehensive documentation, 'manual.do.txt', to
various formats. The 'make.sh' script runs a set of translations.
# #include "../manual/_install.do.txt"
```

# Doconce: Document Once, Include Anywhere

Hans Petter Langtangen<sup>1,2</sup>

<sup>1</sup>Simula Research Laboratory <sup>2</sup>University of Oslo

Mar 11, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LATEX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

# 1 The Doconce Concept

Doconce is two things:

1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LATEX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2\* programs) go to XML, HTML, LATEX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LATEX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.

2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

#### Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than Lagrange and HTML.
- Doconce can be converted to plain *untagged* text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files.
- Doconce has full support for LaTeX math, and integrates very well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LATEX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is obviously a superior tool.

#### Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants
  to appear as plain untagged text for viewing in Pydoc, as reStructuredText
  for use with Sphinx, as wiki text when publishing the software at web sites,
  and as LATEX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount
  of Doconce tagging is added, before the memos can appear as Sphinx
  web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover,

Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LATEX, Sphinx, and similar formats.

#### 2 What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- · Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing bc! (begin code) and ec! (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing bt! (begin TeX) and et! (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTEX and text-like inline mathematics.
- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.

- · Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
===== A Subsection with Sample Text =====
label{my:first:sec}
```

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1 \* item 2 \* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2 o item 3

URLs with a link word are possible, as in "hpl":"http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL":"tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

  time	   velocity	acceleration
r-   0.0   2.0   4.0	1.4186   1.376512   1.1E+1	r   -5.01   11.919   14.717624

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

#### A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, emphasized words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an o (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section 2.1.

Doconce also allows inline comments such as (hpl: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section 3 for an example).

Tables are also supperted, e.g.,

velocity	acceleration
1.4186	-5.01
1.376512	11.919
1.1E+1	14.717624
	1.4186 1.376512

#### **Mathematics and Computer Code**

Inline mathematics, such as  $\nu = \sin(x)$ , allows the formula to be specified both as LATEX and as plain text. This results in a professional LATEX typesetting, but in other formats the text version normally looks better than raw LATEX mathematics with backslashes. An inline formula like  $\nu = \sin(x)$  is typeset as

$$\ln = \sin(x)$$
 =  $\sin(x)$ 

The pipe symbol acts as a delimiter between LATEX code and the plain text version of the formula.

Blocks of mathematics are better typeset with raw LATEX, inside bt! and et! (begin tex / end tex) instructions. The result looks like this:

$$\begin{array}{lcl} \frac{\partial u}{\partial t} & = & \nabla^2 u + f, \\ \frac{\partial v}{\partial t} & = & \nabla \cdot (q(u)\nabla v) + g \end{array} \tag{1}$$

$$\frac{\partial v}{\partial t} = \nabla \cdot (q(u)\nabla v) + g$$
 (2)

Of course, such blocks only looks nice in LaTeX. The raw LaTeX syntax appears in all other formats (but can still be useful for those who can read LaTeX syntax).

You can have blocks of computer code, starting and ending with bc! and ec! instructions, respectively. Such blocks look like

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., bc xxx! where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

```
# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
```

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with bc pro!, while a part of a file is copied into a bc cod! environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LATEX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

# 2.3 Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style <code>newcommand</code> construction. The newcommands defined in a file with name <code>newcommand\_replace.tex</code> are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names <code>newcommands.tex</code> and <code>newcommands\_keep.tex</code> are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX

math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by bt! and et! in newcommands\_keep.tex to keep them unchanged, at least if they contribute to make the raw LTEX math text easier to read in the formats that cannot render LTEX. Newcommands used elsewhere throughout the text will usually be placed in newcommands\_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands\*.tex files must appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LATEX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LATEX, making it easy for Doconce documents to be integrated in LATEX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

#### 3 From Doconce to Other Formats

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

Terminal> doconce format format mydoc.do.txt	
or just	
Terminal> doconce format format mydoc	
The mako or preprocess programs are always used to preprocess the file file and options to mako or preprocess can be added after the filename. For example,	
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5 # p	 reproces:

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

Terminal> doconce format latex yourdoc extra\_sections=True VAR1=5 # mako

Inline comments in the text are removed from the output by

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal> doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

#### **3.1 HTML**

Making an HTML version of a Doconce file mydoc.do.txt is performed by

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing.

#### 3.2 Pandoc

Output in the versatile Pandoc format results from

```
Terminal> doconce format pandoc mydoc
```

The name of the output file is mydoc.pnd. From this format one can go to numerous other formats:

```
Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd
Terminal> pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd
```

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or Latex to the output format instead of ignoring it. See the Pandoc documentation for the many features of the pandoc program.

#### 3.3 LATEX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps:

**Step 1.** Filter the doconce text to a pre-LaTeX form mydoc.p.tex for ptex2tex:

Terminal	
Terminal> doconce format latex mydoc	
LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands_keep.tex, or newcommands_replace. (see Section 2.3). If these files are present, they are included in the LATEX document so that your commands are defined.	tex
Step 2. Run ptex2tex (if you have it) to make a standard LATEX file,	
Terminal> ptex2tex mydoc	
or just perform a plain copy,	
Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LATEX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run	
Terminal> ptex2tex -DHELVETICA mydoc	
The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTEX "maketitle" heading is also available through	
Terminal> ptex2tex -DLATEX_HEADING=traditional mydoc	
A separate titlepage can be generate by	

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any bc! command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., bc cod! for a code snippet, where cod is set to a certain environment in .ptex2tex.cfg (e.g., CodeIntended). There are over 30 styles to choose from.

\_ Terminal \_

Terminal> ptex2tex -DLATEX\_HEADING=titlepage mydoc

**Step 2b (optional).** Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section\* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are some examples:

```
Terminal> doconce replace 'section{' 'section*{' mydoc.tex}
Terminal> doconce subst 'title\{(.+)Using (.+)\}' \
    'title{\g<1> \\\\ [1.5mm] Using \g<2>' mydoc.tex
```

A lot of tailored fixes to the LATEX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LATEX file.

**Step 3.** Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to use the Minted\_Python, Minted\_Cpp, etc., environments in ptex2tex for typesetting code (specified, e.g., in the \*pro and \*cod environments in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LATEX package is needed. This package is included by running doconce format with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

#### 3.4 PDFLaTeX

Running pdflatex instead of latex follows almost the same steps, but the start is

```
Terminal doconce format latex mydoc

Then ptex2tex is run as explained above, and finally

Terminal pdflatex -shell-escape mydoc
Terminal makeindex mydoc # if index
Terminal bibitem mydoc # if bibliography
Terminal pdflatex -shell-escape mydoc
```

#### 3.5 Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

#### 3.6 reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal> doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and Latex mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from Latex to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html
- http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

#### 3.7 Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx\_dir command:

```
Terminal> doconce sphinx_dir author="authors' names" \
    title="some title" version=1.0 dirname=sphinxdir \
    theme=mytheme file1 file2 file3 ...
```

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs

Terminal> doconce sphinx\_dir mydoc

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx\_dir command generates a script automake-sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake-sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

Te doconce sphinx\_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake-sphinx.py must be edited accordingly. Links to local files (not http: or file: URLs) must be placed in the \_static subdirectory of the Sphinx directory. The utility doconce sphinxfix\_localURLs is run to check for local links: for each such link, say dir1/dir2/myfile.txt it replaces the link by \_static/myfile.txt and copies dir1/dir2/myfile.txt to a local \_static directory (in the same directory as the script is run). The user must copy all \_static/\* files to the \_static subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the \_static subdirectory of the Sphinx directory. It may be wise to place relevant files in a \_static directory and link to these directly from the Doconce document - then links to not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the <code>conf.py</code> configuration file for Sphinx is edited accordingly, and a script <code>make-themes.sh</code> can make HTML documents with one or more themes. For example, to realize the themes <code>fenics</code> and <code>pyramid</code>, one writes

```
Terminal> ./make-themes.sh fenics pyramid
```

The resulting directories with HTML documents are \_build/html\_fenics and \_build/html\_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

**Step 1.** Translate Doconce into the Sphinx format:

Terminal> doconce format sphinx mydoc

**Step 2.** Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
Terminal
mkdir sphinx-rootdir
sphinx-quickstart <<EOF</pre>
sphinx-rootdir
Name of My Sphinx Document
Author
version
version
.rst
index
n
У
n
n
n
n
У
'n
n
y
y
y
EOF
```

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx\_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

**Step 3.** Copy the mydoc.rst file to the Sphinx root directory:

```
Terminal> cp mydoc.rst sphinx-rootdir
```

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the \_static directory, see comment above.

**Step 4.** Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes

```
.. toctree::
    :maxdepth: 2
    mydoc
```

(The spaces before mydoc are important!)

**Step 5.** Generate, for instance, an HTML version of the Sphinx source:

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LTEX, PDF (via LTEX), pure text, man pages, and Texinfo files.

**Step 6.** View the result:

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows bc!: cod gives Python (code-block:: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LTFX output.

#### 3.8 Google Code Wiki

There are several different wiki dialects, but Doconce only support the one used by Google Code. The transformation to this format, called <code>gwiki</code> to explicitly mark it as the Google Code dialect, is done by

```
Terminal> doconce format gwiki mydoc.do.txt
```

You can then open a new wiki page for your Google Code project, copy the mydoc.gwiki output file from doconce format and paste the file contents into the wiki page. Press **Preview** or **Save Page** to see the formatted result.

When the Doconce file contains figures, each figure filename must be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

#### 3.9 Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to re-StructuredText. Since Doconce does not know if the .rst file is going to be

filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

#### **3.10 Demos**

The current text is generated from a Doconce format stored in the file

```
docs/tutorial/tutorial.do.txt
```

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

#### 3.11 Dependencies and Installation

Doconce itself is pure Python code hosted at <a href="http://code.google.com/p/doconce">http://code.google.com/p/doconce</a>. Its installation from the Mercurial (hg) source follows the standard procedure:

```
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
```

If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess cd preprocess cd doconce sudo python setup.py install cd ..
```

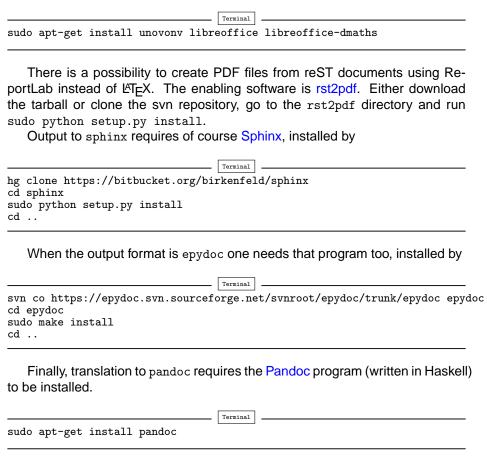

A much more advanced alternative to Preprocess is Mako. Its installation is most conveniently done by pip,

```
Terminal
pip install Mako
This command requires pip to be installed. On Debian Linux systems, such as
Ubuntu, the installation is simply done by
sudo apt-get install python-pip
Alternatively, one can install from the pip source code.
   To make LATEX documents (without going through the reStructuredText for-
mat) you need ptex2tex, which is installed by
                                 Terminal
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
As seen, cp2texmf.sh copies some special stylefiles that that ptex2tex poten-
tially makes use of. Some more standard stylefiles are also needed. These are
installed by
                                 __ Terminal
sudo apt-get install texlive-latex-extra
on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with
the necessary stylefiles (if not, they can be found by googling and installed
manually in the ~/texmf/tex/latex/misc directory).
   The minted LATEX style is offered by ptex2tex and popular among users.
This style requires the package Pygments:
                                 __ Terminal _
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
If you use the minted style, you have to enable it by running ptex2tex -DMINTED
and then latex -shell-escape, see the Section 3.
   For rst output and further transformation to LATEX, HTML, XML, OpenOffice,
and so on, one needs docutils. The installation can be done by
                                 Terminal
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
```

cd docutils

cd ..

sudo python setup.py install

To use the OpenOffice suite you will typically on Debian systems install

**Remark.** Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install. Doconce itself is frequently updated so these commands should be run regularly.

# **Doconce: Document Once, Include Anywhere**

Author: Hans Petter Langtangen

Date: Mar 11, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki?
   Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

# **The Doconce Concept**

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2\* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain *untagged* text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files.
- Doconce has full support for LaTeX math, and integrates very well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is obviously a superior tool.

Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one
  wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the
  software at web sites, and as LaTeX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

#### What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
===== A Subsection with Sample Text ===== label{my:first:sec}
```

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2

\* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl":"http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL":"tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r-	r	
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
j		

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

#### A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an o (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2

#### 3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section A Subsection with Sample Text.

Doconce also allows inline comments such as (**hpl**: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section From Doconce to Other Formats for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624

#### **Mathematics and Computer Code**

Inline mathematics, such as  $v = \sin(x)$ , allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like  $v = \sin(x)$  is typeset as:

```
\ln = \sin(x)  v = \sin(x)
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions. The result looks like this:

```
\begin{eqnarray}
{\partial u\over\partial t} &=& \nabla^2 u + f, label{myeq1}\\
{\partial v\over\partial t} &=& \nabla\cdot(q(u)\nabla v) + g
\end{eqnarray}
```

Of course, such blocks only looks nice in LaTeX. The raw LaTeX syntax appears in all other formats (but can still be useful for those who can read LaTeX syntax).

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks look like:

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

# Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style <code>newcommand</code> construction. The newcommands defined in a file with name <code>newcommand\_replace.tex</code> are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names <code>newcommands.tex</code> and <code>newcommands\_keep.tex</code> are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by <code>!bt</code> and <code>!et</code> in <code>newcommands\_keep.tex</code> to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in <code>newcommands\_replace.tex</code> and expanded by Doconce. The definitions of newcommands in the <code>newcommands\*.tex</code> files <code>must</code> appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

#### From Doconce to Other Formats

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

```
Terminal> doconce format format mydoc.do.txt

or just:

Terminal> doconce format format mydoc
```

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example:

```
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5  # preprotections + preprote
```

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

Inline comments in the text are removed from the output by:

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal> doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

#### **HTML**

Making an HTML version of a Doconce file mydoc.do.txt is performed by:

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing.

#### **Pandoc**

Output in the versatile Pandoc format results from:

```
Terminal> doconce format pandoc mydoc
```

The name of the output file is mydoc.pnd. From this format one can go to numerous other formats:

```
Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd
Terminal> pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd
```

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it. See the Pandoc documentation for the many features of the pandoc program.

#### LaTeX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps: .. Note: putting code blocks inside a list is not successful in many

#### Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for ptex2tex:

```
Terminal> doconce format latex mydoc
```

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands\_keep.tex, or newcommands\_replace.tex (see the section Macros (Newcommands), Cross-References, Index, and Bibliography). If these files are present, they are included in the LaTeX document so that your commands are defined.

Step 2. Run ptex2tex (if you have it) to make a standard LaTeX file:

```
Terminal> ptex2tex mydoc
or just perform a plain copy:
Terminal> cp mydoc.p.tex mydoc.tex
```

Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run:

```
Terminal> ptex2tex -DHELVETICA mydoc
```

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through:

```
Terminal> ptex2tex -DLATEX_HEADING=traditional mydoc
```

A separate titlepage can be generate by:

```
Terminal> ptex2tex -DLATEX_HEADING=titlepage mydoc
```

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc cod for a code snippet, where cod is set to a certain environment in .ptex2tex.cfg (e.g., CodeIntended). There are over 30 styles to choose from.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section\* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are some examples:

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

Step 3. Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to use the Minted\_Python, Minted\_Cpp, etc., environments in ptex2tex for typesetting code (specified, e.g., in the \*pro and \*cod environments in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LaTeX package is needed. This package is included by running doconce format with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

#### **PDFLaTeX**

Running pdflatex instead of latex follows almost the same steps, but the start is:

```
Terminal> doconce format latex mydoc
```

Then ptex2tex is run as explained above, and finally:

```
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> pdflatex -shell-escape mydoc
```

#### **Plain ASCII Text**

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

#### reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal > doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run:

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html
- http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

#### **Sphinx**

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx\_dir command:

```
Terminal> doconce sphinx_dir author="authors' names" \
    title="some title" version=1.0 dirname=sphinxdir \
    theme=mytheme file1 file2 file3 ...
```

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs:

Terminal > doconce sphinx\_dir mydoc

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx\_dir command generates a script automake-sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake-sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

Te doconce sphinx\_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake-sphinx.py must be edited accordingly. Links to local files (not http: or file: URLs) must be placed in the \_static subdirectory of the Sphinx directory. The utility doconce sphinxfix\_localURLs is run to check for local links: for each such link, say dir1/dir2/myfile.txt it replaces the link by \_static/myfile.txt and copies dir1/dir2/myfile.txt to a local \_static directory (in the same directory as the script is run). The user must copy all \_static/\* files to the \_static subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the \_static subdirectory of the Sphinx directory. It may be wise to place relevant files in a \_static directory and link to these directly from the Doconce document - then links to not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the conf.py configuration file for Sphinx is edited accordingly, and a script make-themes. sh can make HTML documents with one or more themes. For example, to realize the themes fenics and pyramid, one writes:

```
Terminal> ./make-themes.sh fenics pyramid
```

The resulting directories with HTML documents are \_build/html\_fenics and \_build/html\_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format:

```
Terminal> doconce format sphinx mydoc
```

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
n
-
Name of My Sphinx Document
Author</pre>
```

```
version
version
.rst
index
n
У
n
n
n
n
У
n
n
У
У
У
EOF
```

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx\_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

Step 3. Copy the mydoc.rst file to the Sphinx root directory:

```
Terminal> cp mydoc.rst sphinx-rootdir
```

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the \_static directory, see comment above.

Step 4. Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes:

```
.. toctree::
    :maxdepth: 2

    mydoc

(The spaces before mydoc are important!)

Step 5. Generate, for instance, an HTML version of the Sphinx source:

make clean  # remove old versions
```

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

*Step 6.* View the result:

make html

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows !bc: cod gives Python (code-block: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

#### Google Code Wiki

There are several different wiki dialects, but Doconce only support the one used by Google Code. The transformation to this format, called gwiki to explicitly mark it as the Google Code dialect, is done by:

```
Terminal> doconce format gwiki mydoc.do.txt
```

You can then open a new wiki page for your Google Code project, copy the mydoc.gwiki output file from doconce format and paste the file contents into the wiki page. Press **Preview** or **Save Page** to see the formatted result.

When the Doconce file contains figures, each figure filename must be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

#### Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

#### **Demos**

The current text is generated from a Doconce format stored in the file:

```
docs/tutorial/tutorial.do.txt
```

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

#### **Dependencies and Installation**

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hg) source follows the standard procedure:

```
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
```

If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
cd ..
```

A much more advanced alternative to Preprocess is Mako. Its installation is most conveniently done by pip:

```
pip install Mako
```

This command requires pip to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by:

```
sudo apt-get install python-pip
```

Alternatively, one can install from the pip source code.

To make LaTeX documents (without going through the reStructuredText format) you need ptex2tex, which is installed by:

```
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
```

As seen, cp2texmf.sh copies some special stylefiles that that ptex2tex potentially makes use of. Some more standard stylefiles are also needed. These are installed by:

```
sudo apt-get install texlive-latex-extra
```

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the ~/texmf/tex/latex/misc directory).

The *minted* LaTeX style is offered by ptex2tex and popular among users. This style requires the package Pygments:

```
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments cd pygments sudo python setup.py install
```

If you use the minted style, you have to enable it by running ptex2tex -DMINTED and then latex -shell-escape, see the the section From Doconce to Other Formats.

For rst output and further transformation to LaTeX, HTML, XML, OpenOffice, and so on, one needs docutils. The installation can be done by:

```
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/doc
cd docutils
sudo python setup.py install
cd ..
```

To use the OpenOffice suite you will typically on Debian systems install:

```
sudo apt-get install unovonv libreoffice libreoffice-dmaths
```

There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is rst2pdf. Either download the tarball or clone the svn repository, go to the rst2pdf directory and run sudo python setup.py install.

```
system-message
WARNING/2 in tutorial.rst, line 399
Duplicate explicit target name: "sphinx".
```

Output to sphinx requires of course Sphinx, installed by:

```
hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
cd ..
```

When the output format is epydoc one needs that program too, installed by:

```
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ..
```

Finally, translation to pandoc requires the Pandoc program (written in Haskell) to be installed:

```
sudo apt-get install pandoc
```

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install. Doconce itself is frequently updated so these commands should be run regularly.

# DOCONCE: DOCUMENT ONCE, INCLUDE ANYWHERE

Author Hans Petter Langtangen

**Date** Mar 11, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

## THE DOCONCE CONCEPT

#### Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2\* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

#### Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain untagged text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files
- Doconce has full support for LaTeX math, and integrates very well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated
  markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make
  the initial versions of a Sphinx or wiki document.
- Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is obviously a superior tool.

#### Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

## WHAT DOES DOCONCE LOOK LIKE?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
==== A Subsection with Sample Text =====
label{my:first:sec}
```

```
Ordinary text looks like ordinary text, and the tags used for
_boldface_ words, *emphasized* words, and 'computer' words look
natural in plain text. Lists are typeset as you would do in an email,
  * item 1
  * item 2
  * item 3
Lists can also have automatically numbered items instead of bullets,
 o item 1
 o item 2
 o item 3
URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl".
If the word is URL, the URL itself becomes the link name,
as in "URL": "tutorial.do.txt".
References to sections may use logical names as labels (e.g., a
"label" command right after the section title), as in the reference to
Section ref{my:first:sec}.
Doconce also allows inline comments such as [hpl: here I will make
some remarks to the text] for allowing authors to make notes. Inline
comments can be removed from the output by a command-line argument
(see Section ref{doconce2formats} for an example).
```

Tables are also supperted, e.g.,

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

## 3.1 A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an ○ (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section A Subsection with Sample Text.

Doconce also allows inline comments such as (**hpl**: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section *From Doconce to Other Formats* for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624

### 3.2 Mathematics and Computer Code

Inline mathematics, such as  $\nu = \sin(x)$ , allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like  $\nu = \sin(x)$  is typeset as

```
\alpha = \sin(x) = \sin(x)
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions. The result looks like this:

$$\begin{split} \frac{\partial u}{\partial t} &= \nabla^2 u + f, \\ \frac{\partial v}{\partial t} &= \nabla \cdot (q(u)\nabla v) + g \end{split} \tag{3.1}$$

Of course, such blocks only looks nice in LaTeX. The raw LaTeX syntax appears in all other formats (but can still be useful for those who can read LaTeX syntax).

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks look like

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

# 3.3 Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style newcommand construction. The newcommands defined in a file with name newcommand\_replace.tex are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names newcommands.tex and newcommands\_keep.tex are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by !bt and !et in newcommands\_keep.tex to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in newcommands\_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands\*.tex files must appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

## FROM DOCONCE TO OTHER FORMATS

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

Terminal> doconce format format mydoc.do.txt

#### or just

Terminal> doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example,

```
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5  # preprocess Terminal> doconce format latex yourdoc extra_sections=True VAR1=5  # mako
```

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

Inline comments in the text are removed from the output by

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal > doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

#### **4.1 HTML**

Making an HTML version of a Doconce file mydoc.do.txt is performed by

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing.

#### 4.2 Pandoc

Output in the versatile Pandoc format results from

Terminal> doconce format pandoc mydoc

The name of the output file is mydoc.pnd. From this format one can go to numerous other formats:

```
Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd Terminal> pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd
```

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it. See the Pandoc documentation for the many features of the pandoc program.

#### 4.3 LaTeX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps: .. Note: putting code blocks inside a list is not successful in many

#### Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for ptex2tex:

```
Terminal> doconce format latex mydoc
```

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands\_keep.tex, or newcommands\_replace.tex (see the section *Macros* (*Newcommands*), *Cross-References*, *Index*, *and Bibliography*). If these files are present, they are included in the LaTeX document so that your commands are defined.

Step 2. Run ptex2tex (if you have it) to make a standard LaTeX file,

Terminal> ptex2tex mydoc

or just perform a plain copy,

Terminal> cp mydoc.p.tex mydoc.tex

Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run

```
Terminal> ptex2tex -DHELVETICA mydoc
```

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through

```
Terminal> ptex2tex -DLATEX_HEADING=traditional mydoc
```

#### A separate titlepage can be generate by

```
Terminal> ptex2tex -DLATEX_HEADING=titlepage mydoc
```

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc cod for a code snippet, where cod is set to a certain environment in .ptex2tex.cfg (e.g., CodeIntended). There are over 30 styles to choose from.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section\* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are some examples:

```
Terminal> doconce replace 'section{' 'section*{' mydoc.tex Terminal> doconce subst 'title\{(.+)Using (.+)\}' \ 'title{\g<1> \\\ [1.5mm] Using \g<2>' mydoc.tex
```

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

Step 3. Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to use the Minted\_Python, Minted\_Cpp, etc., environments in ptex2tex for typesetting code (specified, e.g., in the \*pro and \*cod environments in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LaTeX package is needed. This package is included by running doconce format with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

#### 4.4 PDFLaTeX

Running pdflatex instead of latex follows almost the same steps, but the start is

```
Terminal> doconce format latex mydoc
```

Then ptex2tex is run as explained above, and finally

```
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> pdflatex -shell-escape mydoc
```

#### 4.5 Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

4.4. PDFLaTeX

#### 4.6 reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal> doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html
- http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

## 4.7 Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx\_dir command:

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs

```
Terminal> doconce sphinx_dir mydoc
```

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx\_dir command generates a script automake-sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake-sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

Te doconce sphinx\_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake-sphinx.py must be edited accordingly. Links to local files (not http: or file: URLs) must be placed in the \_static subdirectory of the Sphinx directory. The utility doconce sphinxfix\_localURLs is run to check for local links: for each such link, say dir1/dir2/myfile.txt it replaces the link by \_static/myfile.txt and copies dir1/dir2/myfile.txt to a local \_static directory (in the same directory as the script is run). The user must copy all \_static/\* files to the \_static subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the \_static subdirectory of the Sphinx directory. It may be wise to place relevant files in a \_static directory and link to these directly from the Doconce document - then links to not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the <code>conf.py</code> configuration file for Sphinx is edited accordingly, and a script <code>make-themes.sh</code> can make HTML documents with one or more themes. For example, to realize the themes <code>fenics</code> and <code>pyramid</code>, one writes

```
Terminal> ./make-themes.sh fenics pyramid
```

The resulting directories with HTML documents are \_build/html\_fenics and \_build/html\_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format:

```
Terminal> doconce format sphinx mydoc
```

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
n
__
Name of My Sphinx Document
Author
version
version
.rst
index
n
y
n
n
n
n
n</pre>
```

4.7. Sphinx 15

n n y y y EOF

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx\_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

Step 3. Copy the mydoc.rst file to the Sphinx root directory:

```
Terminal> cp mydoc.rst sphinx-rootdir
```

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the \_static directory, see comment above.

Step 4. Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes

```
.. toctree::
   :maxdepth: 2
   mydoc
```

(The spaces before mydoc are important!)

Step 5. Generate, for instance, an HTML version of the Sphinx source:

```
make clean  # remove old versions
make html
```

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

Step 6. View the result:

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows !bc: cod gives Python (code-block: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

## 4.8 Google Code Wiki

There are several different wiki dialects, but Doconce only support the one used by Google Code. The transformation to this format, called <code>gwiki</code> to explicitly mark it as the Google Code dialect, is done by

```
Terminal > doconce format gwiki mydoc.do.txt
```

You can then open a new wiki page for your Google Code project, copy the mydoc.gwiki output file from doconce format and paste the file contents into the wiki page. Press **Preview** or **Save Page** to see the formatted result.

When the Doconce file contains figures, each figure filename must be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

## 4.9 Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

#### **4.10 Demos**

The current text is generated from a Doconce format stored in the file

```
docs/tutorial/tutorial.do.txt
```

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

## 4.11 Dependencies and Installation

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hg) source follows the standard procedure:

```
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
```

If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
cd ..
```

A much more advanced alternative to Preprocess is Mako. Its installation is most conveniently done by pip,

```
pip install Mako
```

This command requires pip to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by

```
sudo apt-get install python-pip
```

Alternatively, one can install from the pip source code.

To make LaTeX documents (without going through the reStructuredText format) you need ptex2tex, which is installed by

```
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
```

As seen, cp2texmf.sh copies some special stylefiles that that ptex2tex potentially makes use of. Some more standard stylefiles are also needed. These are installed by

```
sudo apt-get install texlive-latex-extra
```

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the ~/texmf/tex/latex/misc directory).

The minted LaTeX style is offered by ptex2tex and popular among users. This style requires the package Pygments:

```
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
```

If you use the minted style, you have to enable it by running ptex2tex -DMINTED and then latex -shell-escape, see the the section *From Doconce to Other Formats*.

For rst output and further transformation to LaTeX, HTML, XML, OpenOffice, and so on, one needs docutils. The installation can be done by

```
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
cd docutils
sudo python setup.py install
cd ..
```

To use the OpenOffice suite you will typically on Debian systems install

```
sudo apt-get install unovonv libreoffice libreoffice-dmaths
```

There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is rst2pdf. Either download the tarball or clone the svn repository, go to the rst2pdf directory and run sudo python setup.py install.

Output to sphinx requires of course Sphinx, installed by

```
hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
cd ..
```

When the output format is epydoc one needs that program too, installed by

```
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ..
```

Finally, translation to pandoc requires the Pandoc program (written in Haskell) to be installed.

```
sudo apt-get install pandoc
```

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install. Doconce itself is frequently updated so these commands should be run regularly.

Doconce: Document Once, Include Anywhere

Hans Petter Langtangen [1, 2]

- [1] Simula Research Laboratory
- [2] University of Oslo

Date: Mar 11, 2012

- \* When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- \* Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX (http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf), HTML (http://www.htmlcodetutorial.com/), reStructuredText (http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html), Sphinx (http://sphinx.pocoo.org/contents.html), and wiki (http://code.google.com/p/support/wiki/WikiSyntax)? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

\* Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

The Doconce Concept

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2\* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.).

" tutorial.txt

The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

#### Here are some Doconce features:

- \* Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- \* Doconce can be converted to plain \*untagged\* text, often desirable for computer programs and email.
- \* Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files.
- \* Doconce has full support for LaTeX math, and integrates very well with big LaTeX projects (books).
- \* Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- \* Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is obviously a superior tool.

Doconce was particularly written for the following sample applications:

- \* Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- \* Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- \* Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

## " tutorial.txt "

What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- \* Bullet lists arise from lines starting with an asterisk.
- \* \*Emphasized words\* are surrounded by asterisks.
- \* \_Words in boldface\_ are surrounded by underscores.
- \* Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- \* Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- \* Paragraph headings are recognized by a double underscore before and after the heading.
- \* The abstract of a document starts with \*Abstract\* as paragraph heading, and all text up to the next heading makes up the abstract,
- \* Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- \* Blocks of computer code can also be imported from source files.
- \* Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- \* There is support for both LaTeX and text-like inline mathematics.
- \* Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- \* Invisible comments in the output format can be inserted throughout the text.
- \* Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- \* There is special support for advanced exercises features.
- \* With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- \* With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

#### tutorial.txt

Here is an example of some simple text written in the Doconce format::

==== A Subsection with Sample Text =====
label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl"

If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
	' 	

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2

,,

" tutorial.txt "

\* item 3

Lists can also have numbered items instead of bullets, just use an o (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in hpl (http://folk.uio.no/hpl). If the word is URL, the URL itself becomes the link name, as in tutorial.do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section "A Subsection with Sample Text".

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section "From Doconce to Other Formats" for an example).

Tables are also supperted, e.g.,

========	========	========
time	velocity	acceleration
========	========	=========
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
=========	=========	=========

Mathematics and Computer Code

Inline mathematics, such as  $v = \sin(x)$ , allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like  $v = \sin(x)$  is typeset as:

```
\ln = \sin(x) | v = \sin(x)
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions.
The result looks like this::

```
\begin{eqnarray}
{\partial u\over\partial t} &=& \nabla^2 u + f, label{myeq1}\\
{\partial v\over\partial t} &=& \nabla\cdot(q(u)\nabla v) + g
\end{eqnarray}
```

#### tutorial.txt

Of course, such blocks only looks nice in LaTeX. The raw LaTeX syntax appears in all other formats (but can still be useful for those who can read LaTeX syntax).

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks look like::

from math import sin, pi
def myfunc(x):
 return sin(pi\*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments)::

# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style \*newcommand\* construction. The newcommands defined in a file with name

### tutorial.txt

newcommand\_replace.tex are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names newcommands.tex and newcommands\_keep.tex are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by !bt and !et in newcommands\_keep.tex to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in newcommands\_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands\*.tex files \*must\* appear on a single

line (multi-line newcommands are too hard to parse with regular

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page (https://doconce.googlecode.com/hg/doc/demos/manual/index.html) for various formats of this document).

From Doconce to Other Formats

expressions).

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format::

Terminal> doconce format format mydoc.do.txt or just::

Terminal > doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example:

Terminal> doconce format latex mydoc -Dextra\_sections -DVAR1=5 # pre process

Terminal> doconce format latex yourdoc extra\_sections=True VAR1=5 # mak o

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is

,,

## tutorial.txt defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex". Inline comments in the text are removed from the output by:: Terminal > doconce format latex mydoc --skip\_inline\_comments One can also remove all such comments from the original Doconce file by running:: Terminal > doconce remove\_inline\_comments mydoc This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed. HTML\_\_\_\_ Making an HTML version of a Doconce file mydoc.do.txt is performed by:: Terminal> doconce format html mydoc The resulting file mydoc.html can be loaded into any web browser for viewing. Pandoc Output in the versatile Pandoc format results from:: Terminal> doconce format pandoc mydoc The name of the output file is mydoc.pnd. From this format one can go to numerous other formats:: Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd Terminal > pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it. See the Pandoc documentation (http://johnmacfarlane.net/pandoc/README.html) for the many features of the pandoc program. LaTeX Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps:

"

\*Step 1.\* Filter the doconce text to a pre-LaTeX form mydoc.p.tex for

ptex2tex::

## tutorial.txt

Terminal> doconce format latex mydoc

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands\_keep.tex, or newcommands\_replace.tex (see the section "Macros (Newcommands), Cross-References, Index, and Bibliography").

If these files are present, they are included in the LaTeX document so that your commands are defined.

\*Step 2.\* Run ptex2tex (if you have it) to make a standard LaTeX file::

Terminal> ptex2tex mydoc

or just perform a plain copy::

Terminal> cp mydoc.p.tex mydoc.tex

Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run::

Terminal> ptex2tex -DHELVETICA mydoc

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through::

Terminal> ptex2tex -DLATEX\_HEADING=traditional mydoc

A separate titlepage can be generate by::

Terminal> ptex2tex -DLATEX\_HEADING=titlepage mydoc

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc cod for a code snippet, where cod is set to a certain environment in .ptex2tex.cfg (e.g., CodeIntended). There are over 30 styles to choose from.

\*Step 2b (optional).\* Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section\* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are some examples::

"

```
tutorial.txt
        Terminal> doconce replace 'section{' 'section*{' mydoc.tex
        Terminal> doconce subst 'title\{(.+)Using (.+)\}' \
                   'title{\g<1> \\\ [1.5mm] Using \g<2>' mydoc.tex
A lot of tailored fixes to the LaTeX document can be done by
an appropriate set of text replacements and regular expression
substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.
*Step 3.* Compile mydoc.tex
and create the PDF file::
        Terminal> latex mydoc
Terminal> latex mydoc
        Terminal> makeindex mydoc  # if index
        Terminal> bibitem mydoc # if bibliography
        Terminal> latex mydoc
        Terminal> dvipdf mydoc
If one wishes to use the Minted_Python, Minted_Cpp, etc.,
environments in ptex2tex for typesetting code (specified, e.g., in
the *pro and *cod environments in .ptex2tex.cfg or
$HOME/.ptex2tex.cfg), the minted LaTeX package is needed.
package is included by running doconce format with the -DMINTED
option::
        Terminal> ptex2tex -DMINTED mydoc
In this case, latex must be run with the
-shell-escape option::
        Terminal> latex -shell-escape mydoc
        Terminal> latex -shell-escape mydoc
        Terminal> makeindex mydoc # if index
        Terminal> bibitem mydoc
                                    # if bibliography
        Terminal> latex -shell-escape mydoc
        Terminal > dvipdf mydoc
PDFLaTeX
Running pdflatex instead of latex follows almost the same steps,
but the start is::
        Terminal> doconce format latex mydoc
Then ptex2tex is run as explained above, and finally::
        Terminal> pdflatex -shell-escape mydoc
        Terminal> makeindex mydoc # if index
                                    # if bibliography
        Terminal> bibitem mydoc
        Terminal> pdflatex -shell-escape mydoc
```

# tutorial.txt

## Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code::

Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt

### reStructuredText

\_\_\_\_\_

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst::

Terminal > doconce format rst mydoc.do.txt

We may now produce various other formats::

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports \*on the command line\*. Run::

Terminal> unoconv --show

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF::

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

\*Remark about Mathematical Typesetting.\* At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

"

" tutorial.txt "

#### Sphinx

\_\_\_\_\_

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx\_dir command::

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs::

Terminal> doconce sphinx\_dir mydoc

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx\_dir command generates a script automake-sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake-sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

Te doconce sphinx\_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake-sphinx.py must be edited accordingly. Links to local files (not http: or file: URLs) must be placed in the \_static subdirectory of the Sphinx directory. The utility doconce sphinxfix\_localURLs is run to check for local links: for each such link, say dirl/dir2/myfile.txt it replaces the link by \_static/myfile.txt and copies dirl/dir2/myfile.txt to a local \_static directory (in the same directory as the script is run). The user must copy all \_static/\* files to the \_static subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the \_static subdirectory of the Sphinx directory.

It may be wise to place relevant files in a \_static directory and link to these directly from the Doconce document - then links

" tutorial.txt "

to not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the conf.py configuration file for Sphinx is edited accordingly, and a script make-themes.sh can make HTML documents with one or more themes. For example,

to realize the themes fenics and pyramid, one writes::

Terminal> ./make-themes.sh fenics pyramid

The resulting directories with HTML documents are \_build/html\_fenics and \_build/html\_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

\*Step 1.\* Translate Doconce into the Sphinx format::

Terminal> doconce format sphinx mydoc

\*Step 2.\* Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter::

mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
n</pre>

Name of My Sphinx Document Author version

version

.rst

n

y n

n

n

n У

n n

У

У

У

EOF

The autogenerated conf.py file may need some edits if you want to specific layout (Sphinx themes)

## tutorial.txt

of HTML pages. The doconce sphinx\_dir generator makes an extended conv.py file where, among other things, several useful Sphinx extensions are included.

\*Step 3.\* Copy the mydoc.rst file to the Sphinx root directory::

Terminal> cp mydoc.rst sphinx-rootdir

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the \_static directory, see comment above.

\*Step 4.\* Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes::

.. toctree::
 :maxdepth: 2

mydoc

(The spaces before mydoc are important!)

\*Step 5.\* Generate, for instance, an HTML version of the Sphinx source::

make clean # remove old versions
make html

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

\*Step 6.\* View the result::

Terminal> firefox \_build/html/index.html

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows !bc: cod gives Python (code-block:: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

Google Code Wiki

There are several different wiki dialects, but Doconce only support the one used by Google Code (http://code.google.com/p/support/wiki/WikiSyntax). The transformation to this format, called gwiki to explicitly mark

### tutorial.txt

it as the Google Code dialect, is done by::

Terminal > doconce format gwiki mydoc.do.txt

You can then open a new wiki page for your Google Code project, copy the mydoc.gwiki output file from doconce format and paste the file contents into the wiki page. Press \_Preview\_ or \_Save Page\_ to see the formatted result.

When the Doconce file contains figures, each figure filename must be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

# Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename.

The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

### Demos

----

The current text is generated from a Doconce format stored in the file::

docs/tutorial/tutorial.do.txt

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here (https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html) is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

Dependencies and Installation

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hq) source follows the standard procedure::

```
tutorial.txt
        # Doconce
        hq clone https://doconce.googlecode.com/hq/ doconce
        cd doconce
        sudo python setup.py install
        cd ..
If you make use of the Preprocess (http://code.google.com/p/preprocess)
preprocessor, this program must be installed::
        svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
        cd preprocess
        cd doconce
        sudo python setup.py install
A much more advanced alternative to Preprocess is
Mako (http://www.makotemplates.org). Its installation is most
conveniently done by pip::
        pip install Mako
This command requires pip to be installed. On Debian Linux systems,
such as Ubuntu, the installation is simply done by::
        sudo apt-get install python-pip
Alternatively, one can install from the pip source code (http://pypi.python.org/
pypi/pip).
To make LaTeX
documents (without going through the reStructuredText format) you
need ptex2tex (http://code.google.com/p/ptex2tex), which is
installed by::
        svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
        cd ptex2tex
        sudo python setup.py install
        cd latex
        sh cp2texmf.sh # copy stylefiles to ~/texmf directory
        cd ../..
As seen, cp2texmf.sh copies some special stylefiles that
that ptex2tex potentially makes use of. Some more standard stylefiles
are also needed. These are installed by::
        sudo apt-get install texlive-latex-extra
on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with
the necessary stylefiles (if not, they can be found by googling and installed
manually in the ~/texmf/tex/latex/misc directory).
```

```
tutorial.txt
The *minted* LaTeX style is offered by ptex2tex and popular among
users. This style requires the package Pygments (http://pygments.org)::
        hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
        cd pygments
        sudo python setup.py install
If you use the minted style, you have to enable it by running
ptex2tex -DMINTED and then latex -shell-escape, see
the the section "From Doconce to Other Formats".
For rst output and further transformation to LaTeX, HTML, XML,
OpenOffice, and so on, one needs docutils (http://docutils.sourceforge.net).
The installation can be done by::
        svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/
docutils
        cd docutils
        sudo python setup.py install
To use the OpenOffice suite you will typically on Debian systems install::
        sudo apt-get install unovonv libreoffice libreoffice-dmaths
There is a possibility to create PDF files from reST documents
using ReportLab instead of LaTeX. The enabling software is
rst2pdf (http://code.google.com/p/rst2pdf). Either download the tarball
or clone the svn repository, go to the rst2pdf directory and
run sudo python setup.py install.
Output to sphinx requires of course Sphinx (http://sphinx.pocoo.org),
installed by::
        hg clone https://bitbucket.org/birkenfeld/sphinx
        cd sphinx
        sudo python setup.py install
        cd ..
When the output format is epydoc one needs that program too, installed
by::
        svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc ep
ydoc
        cd epydoc
        sudo make install
        cd ..
Finally, translation to pandoc requires the
Pandoc (http://johnmacfarlane.net/pandoc/) program
```

" tutorial.txt "

(written in Haskell) to be installed::

sudo apt-get install pandoc

\*Remark.\* Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install. Doconce itself is frequently updated so these commands should be run regularly.

<u>,</u>

TITLE: Doconce: Document Once, Include Anywhere

BY: Hans Petter Langtangen (Simula Research Laboratory, and University of Oslo)D

ATE: today

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?

- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like U{LaTeX<http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCar d.v2.0.pdf>}, U{HTML<http://www.htmlcodetutorial.com/>}, U{reStructuredText<http</pre> ://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html>}, U{Sphinx<http: //sphinx.pocoo.org/contents.html>}, and U{wiki<http://code.google.com/p/support/ wiki/WikiSyntax>}? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

The Doconce Concept 

Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via C{rst2\*} programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via C{unoconv}) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain I{untagged} text,

- often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files.
- Doconce has full support for LaTeX math, and integrates very well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is obviously a superior tool.

Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- I{Emphasized words} are surrounded by asterisks.
- B{Words in boldface} are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset C{verbatim (in a monospace font)}.
- Section headings are recognied by equality  $(C\{=\})$  signs before and after the title, and the number of  $C\{=\}$  signs indicates the level of the section: 7 for main section, 5 for subsection, and

- 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with I{Abstract} as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing C{!bc} (begin code) and C{!ec} (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing C{!bt} (begin TeX) and C{!et} (end TeX) commands at separate lines before and after the math block.
  There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables,
  - URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format::

```
==== A Subsection with Sample Text =====
label{my:first:sec}
```

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl"

If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument

(see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration		
r	r	r		
0.0	1.4186	-5.01		
2.0	1.376512	11.919		
4.0	1.1E+1	14.717624		
	<u>-</u>	· 		

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for B{boldface} words, I{emphasized} words, and C{computer} words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an C{o} (for ordered) instead of the asterisk:

- 1. item 1 2. item 2
- 3. item 3

URLs with a link word are possible, as in U{hpl<http://folk.uio.no/hpl>}. If the word is URL, the URL itself becomes the link name, as in U{tutorial.do.txt<tutorial.do.txt>}.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section "A Subsection with Sample Text".

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section "From Doconce to Other Formats" for an example).

Tables are also supperted, e.g.,

========	========	========
time	velocity	acceleration
========	========	========
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
========	=========	========

Mathematics and Computer Code

Inline mathematics, such as  $M\{v = \sin(x)\}$ , allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like  $M\{v = \sin(x)\}$  is typeset as:

NOTE: A verbatim block has been removed because it causes problems for Epytext.

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula.

Blocks of mathematics are better typeset with raw LaTeX, inside  $C\{!bt\}$  and  $C\{!et\}$  (begin tex / end tex) instructions. The result looks like this::

NOTE: A verbatim block has been removed because it causes problems for Epytext.

Of course, such blocks only looks nice in LaTeX. The raw LaTeX syntax appears in all other formats (but can still be useful for those who can read LaTeX syntax).

You can have blocks of computer code, starting and ending with C{!bc} and C{!ec} instructions, respectively. Such blocks look like::

from math import sin, pi
def myfunc(x):
 return sin(pi\*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)

A code block must come after some plain sentence (at least for successful output to  $C\{sphinx\}$ ,  $C\{rst\}$ , and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., C{!bc xxx} where C{xxx} is an identifier like C{pycod} for code snippet in Python, C{sys} for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in C{ptex2tex} and defined in a configuration file C{.ptext2tex.cfg}, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments)::

 $\begin{tabular}{ll} \# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console \\ By default, C\{pro\} and C\{cod\} are C\{python\}, C\{sys\} is C\{console\}, \\ \end{tabular}$ 

while  $C\{xpro\}$  and  $C\{xcod\}$  are computer language specific for  $C\{x\}$  in  $C\{f\}$  (Fortran),  $C\{c\}$  (C),  $C\{cpp\}$  (C++),  $C\{pl\}$  (Perl),  $C\{m\}$  (Matlab),  $C\{sh\}$  (Unix shells),  $C\{cy\}$  (Cython), and  $C\{py\}$  (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with C{!bc pro}, while a part of a file is copied into a C{!bc cod} environment. What C{pro} and C{cod} mean is then defined through a C{.ptex2tex.cfg} file for LaTeX and a C{sphinx code-blocks} comment for Sphinx.

Another document can be included by writing  $C\{\# include \# mynote.do.txt \}$  on a line starting with (another) hash sign. Doconce documents have extension  $C\{do.txt\}$ . The  $C\{do\}$  part stands for doconce, while the trailing  $C\{.txt\}$  denotes a text document so that editors gives you the right writing environment for plain text.

Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style I{newcommand} construction. The newcommands defined in a file with name C{newcommand\_replace.tex} are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names C{newcommands.tex} and C{newcommands\_keep.tex} are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by C{!bt} and C{!et} in C{newcommands\_keep.tex} to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in C{newcommands\_replace.tex} and expanded by Doconce. The definitions of newcommands in the  $C\{newcommands*.tex\}$  files  $I\{must\}$  appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the C{doc/manual/manual.do.txt} file (see the U{demo page<https://doconce.googlecode.com/hg/doc/demos/manual/index.html>} for various formats of this document).

31

# tutorial.epytext From Doconce to Other Formats Transformation of a Doconce document C{mydoc.do.txt} to various other formats applies the script C{doconce format}:: Terminal> doconce format format mydoc.do.txt or just:: Terminal > doconce format format mydoc The $C\{mako\}$ or $C\{preprocess\}$ programs are always used to preprocess the file first, and options to $C\{mako\}$ or $C\{preprocess\}$ can be added after the filename. For example:: Terminal> doconce format latex mydoc -Dextra\_sections -DVAR1=5 # pre process Terminal > doconce format latex yourdoc extra\_sections=True VAR1=5 # mak The variable C{FORMAT} is always defined as the current format when running C{preprocess}. That is, in the last example, C{FORMAT} is defined as C{latex}. Inside the Doconce document one can then perform format specific actions through tests like C{#if FORMAT == "latex"}. Inline comments in the text are removed from the output by:: Terminal> doconce format latex mydoc --skip\_inline\_comments One can also remove all such comments from the original Doconce file by running:: Terminal> doconce remove\_inline\_comments mydoc This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed. HTMLMaking an HTML version of a Doconce file C{mydoc.do.txt} is performed by:: Terminal> doconce format html mydoc The resulting file C{mydoc.html} can be loaded into any web browser for viewing. Pandoc Output in the versatile Pandoc format results from::

Terminal> doconce format pandoc mydoc

The name of the output file is C{mydoc.pnd}. From this format one can go to numerous other formats::

Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd Terminal> pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd

Pandoc supports C{latex}, C{html}, C{odt} (OpenOffice), C{docx} (Microsoft Word), C{rtf}, C{texinfo}, to mention some. The C{-R} option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it. See the U{Pandoc documentation<a href="http://johnmacfarlane.net/pandoc/README.html">http://johnmacfarlane.net/pandoc/README.html</a>) for the many features of the C{pandoc} program.

LaTeX

Making a LaTeX file C{mydoc.tex} from C{mydoc.do.txt} is done in two steps:

Terminal> doconce format latex mydoc

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files C{newcommands.tex}, C{newcommands\_keep.tex}, or C{newcommands\_replace.tex} (see the section "Macros (Newcommands), Cross-References, Index, and Bibliography").

If these files are present, they are included in the LaTeX document so that your commands are defined.

I{Step 2.} Run C{ptex2tex} (if you have it) to make a standard LaTeX file::

Terminal> ptex2tex mydoc

or just perform a plain copy::

Terminal> cp mydoc.p.tex mydoc.tex

Doconce generates a C{.p.tex} file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run::

Terminal> ptex2tex -DHELVETICA mydoc

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through::

Terminal> ptex2tex -DLATEX\_HEADING=traditional mydoc

A separate titlepage can be generate by::

Terminal> ptex2tex -DLATEX HEADING=titlepage mydoc

The C{ptex2tex} tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any C{!bc} command in the Doconce source you can insert verbatim block styles as defined in your C $\{$ .ptex2tex.cfg $\}$  file, e.g., C $\{$ !bc cod $\}$  for a code snippet, where C $\{$ cod $\}$  is set to a certain environment in C $\{$ .ptex2tex.cfg $\}$  (e.g., C $\{$ CodeIntended $\}$ ). There are over 30 styles to choose from.

I{Step 2b (optional).} Edit the C{mydoc.tex} file to your needs. For example, you may want to substitute C{section} by C{section\*} to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the C{doconce replace} and C{doconce subst} commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are some examples:

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

I{Step 3.} Compile C{mydoc.tex}
and create the PDF file::

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to use the C{Minted\_Python}, C{Minted\_Cpp}, etc., environments in C{ptex2tex} for typesetting code (specified, e.g., in the C{\*pro} and C{\*cod} environments in C{.ptex2tex.cfg} or C{\$HOME/.ptex2tex.cfg}), the C{minted} LaTeX package is needed. This package is included by running C{doconce format} with the C{-DMINTED} option:

Terminal> ptex2tex -DMINTED mydoc

In this case, C{latex} must be run with the
C{-shell-escape} option::

```
tutorial.epytext
       Terminal> latex -shell-escape mydoc
       Terminal> latex -shell-escape mydoc
       Terminal> makeindex mydoc # if index
       Terminal> bibitem mydoc # if bibliography
       Terminal> latex -shell-escape mydoc
       Terminal> dvipdf mydoc
PDFLaTeX
Running C{pdflatex} instead of C{latex} follows almost the same steps,
but the start is::
       Terminal> doconce format latex mydoc
Then C{ptex2tex} is run as explained above, and finally::
       Terminal> pdflatex -shell-escape mydoc
       Terminal> makeindex mydoc # if index
       Terminal> bibitem mydoc # if bibliography
       Terminal> pdflatex -shell-escape mydoc
Plain ASCII Text
We can go from Doconce "back to" plain untagged text suitable for viewing
in terminal windows, inclusion in email text, or for insertion in
computer source code::
       Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
reStructuredText
Going from Doconce to reStructuredText gives a lot of possibilities to
go to other formats. First we filter the Doconce text to a
reStructuredText file C{mydoc.rst}::
       Terminal > doconce format rst mydoc.do.txt
We may now produce various other formats::
       Terminal> rst2html.py mydoc.rst > mydoc.html # html
       Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
       Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
       Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file C{mydoc.odt} can be loaded into OpenOffice and

saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program  $C\{unovonv\}$  to convert between the many formats OpenOffice supports  $I\{on the command line\}$ . Run::

Terminal> unoconv --show

to see all the formats that are supported. For example, the following commands take  $C\{mydoc.odt\}$  to Microsoft Office Open XML format, classic MS Word format, and PDF::

Terminal> unoconv -f ooxml mydoc.odt Terminal> unoconv -f doc mydoc.odt Terminal> unoconv -f pdf mydoc.odt

I{Remark about Mathematical Typesetting.} At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by C{latex} as output and to a wide extent also supported by the C{sphinx} output format. Some links for going from LaTeX to Word are listed below.

- $U\{\text{http://ubuntuforums.org/showthread.php?t=1033441}<\text{http://ubuntuforums.org/showthread.php?t=1033441}\}$

### Sphinx

\_\_\_\_\_

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the C{doconce sphinx\_dir} command::

The keywords  $C\{author\}$ ,  $C\{title\}$ , and  $C\{version\}$  are used in the headings of the Sphinx document. By default,  $C\{version\}$  is 1.0 and the script will try to deduce authors and title from the doconce files  $C\{file1\}$ ,  $C\{file2\}$ , etc. that together represent the whole document. Note that none of the individual Doconce files  $C\{file1\}$ ,  $C\{file2\}$ , etc. should include the rest as their union makes up the whole document. The default value of  $C\{dirname\}$  is  $C\{sphinx-rootdir\}$ . The  $C\{theme\}$  keyword is used to set the theme for design of HTML output from Sphinx (the default theme is  $C\{'default'\}$ ).

With a single-file document in C{mydoc.do.txt} one often just runs::

Terminal> doconce sphinx\_dir mydoc

and then an appropriate Sphinx directory C{sphinx-rootdir} is made with relevant files.

The C{doconce sphinx\_dir} command generates a script C{automake-sphinx.py} for compiling the Sphinx document into an HTML document. One can either run C{automake-sphinx.py} or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

Te C{doconce sphinx\_dir} script copies directories named C{figs} or C{figures} over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, C{automake-sphinx.py} must be edited accordingly.

Links to local files (not C{http:} or C{file:} URLs) must be placed in the C{\_static} subdirectory of the Sphinx directory. The utility C{doconce sphinxfix\_localURLs} is run to check for local links: for each such link, say C{dirl/dir2/myfile.txt} it replaces the link by C{\_static/myfile.txt} and copies C{dirl/dir2/myfile.txt} to a local C{\_static} directory (in the same directory as the script is run). The user must copy all C{\_static/\*} files to the C{\_static} subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the C{\_static} subdirectory of the Sphinx directory.

It may be wise to place relevant files in a C{\_static} directory and link to these directly from the Doconce document - then links to not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the C{conf.py} configuration file for Sphinx is edited accordingly, and a script C{make-themes.sh} can make HTML documents with one or more themes. For example, to realize the themes C{fenics} and C{pyramid}, one writes::

Terminal> ./make-themes.sh fenics pyramid

The resulting directories with HTML documents are C{\_build/html\_fenics} and C{\_build/html\_pyramid}, respectively. Without arguments, C{make-themes.sh} makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file C{mydoc.do.txt}.

I{Step 1.} Translate Doconce into the Sphinx format::

Terminal> doconce format sphinx mydoc

I{Step 2.} Create a Sphinx root directory either manually or by using the interactive C{sphinx-quickstart} program. Here is a scripted version of the steps with the latter::

```
tutorial.epytext
        mkdir sphinx-rootdir
        sphinx-quickstart <<EOF
        sphinx-rootdir
        Name of My Sphinx Document
        Author
        version
        version
        .rst
        index
        У
        n
        n
        n
        n
        У
        n
        n
        У
        У
        У
        EOF
The autogenerated C{conf.py} file
may need some edits if you want to specific layout (Sphinx themes)
of HTML pages. The C{doconce sphinx_dir} generator makes an extended C{conv.py}
file where, among other things, several useful Sphinx extensions
are included.
I{Step 3.} Copy the C{mydoc.rst} file to the Sphinx root directory::
        Terminal> cp mydoc.rst sphinx-rootdir
If you have figures in your document, the relative paths to those will
be invalid when you work with C{mydoc.rst} in the C{sphinx-rootdir}
directory. Either edit C{mydoc.rst} so that figure file paths are correct,
or simply copy your figure directories to C{sphinx-rootdir}. Links to local files in C{mydoc.rst} must be modified to links to
files in the C{_static} directory, see comment above.
I{Step 4.} Edit the generated C{index.rst} file so that C{mydoc.rst}
is included, i.e., add C{mydoc} to the C{toctree} section so that it becomes::
         .. toctree::
            :maxdepth: 2
           mydoc
(The spaces before C{mydoc} are important!)
I{Step 5.} Generate, for instance, an HTML version of the Sphinx source::
        make clean
                      # remove old versions
```

make html

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with C{index.html} files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

I{Step 6.} View the result::

Terminal> firefox \_build/html/index.html

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows  $C\{!bc\}$ :  $C\{cod\}$  gives Python ( $C\{code-block:: python\}$  in Sphinx syntax) and  $C\{cppcod\}$  gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

# Google Code Wiki

There are several different wiki dialects, but Doconce only support the one used by U{Google Code<a href="http://code.google.com/p/support/wiki/WikiSyntax">http://code.google.com/p/support/wiki/WikiSyntax</a>}. The transformation to this format, called C{gwiki} to explicitly mark it as the Google Code dialect, is done by::

Terminal> doconce format gwiki mydoc.do.txt

You can then open a new wiki page for your Google Code project, copy the  $C\{mydoc.gwiki\}$  output file from  $C\{doconce\ format\}$  and paste the file contents into the wiki page. Press  $B\{Preview\}$  or  $B\{Save\ Page\}$  to see the formatted result.

When the Doconce file contains figures, each figure filename must be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

# Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the  $C\{.rst\}$  file is going to be filtered to LaTeX or HTML, it cannot know if  $C\{.eps\}$  or  $C\{.png\}$  is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The  $C\{make.sh\}$  files in  $C\{docs/manual\}$  and  $C\{docs/tutorial\}$  constitute comprehensive examples on how such scripts can be made.

"

Demos

The current text is generated from a Doconce format stored in the file::

docs/tutorial/tutorial.do.txt

The file C{make.sh} in the C{tutorial} directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, C{tutorial.do.txt} is the starting point. Running C{make.sh} and studying the various generated files and comparing them with the original C{tutorial.do.txt} file, gives a quick introduction to how Doconce is used in a real case. U{Here<https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html>} is a sample of how this tutorial looks in different formats.

There is another demo in the  $C\{docs/manual\}$  directory which translates the more comprehensive documentation,  $C\{manual.do.txt\}$ , to various formats. The  $C\{make.sh\}$  script runs a set of translations.

Dependencies and Installation

Doconce itself is pure Python code hosted at  $U\{\text{http://code.google.com/p/doconce< http://code.google.com/p/doconce>}\}$ . Its installation from the Mercurial ( $C\{\text{hg}\}$ ) source follows the standard procedure::

# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..

If you make use of the U{Preprocess<http://code.google.com/p/preprocess>} preprocessor, this program must be installed::

svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
cd ..

A much more advanced alternative to Preprocess is  $U\{Mako<http://www.makotemplates.org>\}$ . Its installation is most conveniently done by  $C\{pip\}::$ 

pip install Mako

This command requires  $C\{pip\}$  to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by::

sudo apt-get install python-pip

,

```
tutorial.epytext
Alternatively, one can install from the C{pip} U{source code<a href="http://pypi.python.">http://pypi.python.</a>
org/pypi/pip>}.
To make LaTeX
documents (without going through the reStructuredText format) you
need U{ptex2tex<http://code.google.com/p/ptex2tex>}, which is
installed by::
        svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
        cd ptex2tex
        sudo python setup.py install
        cd latex
        sh cp2texmf.sh # copy stylefiles to ~/texmf directory
        cd ../..
As seen, C{cp2texmf.sh} copies some special stylefiles that
that C{ptex2tex} potentially makes use of. Some more standard stylefiles are also needed. These are installed by::
        sudo apt-get install texlive-latex-extra
on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with
the necessary stylefiles (if not, they can be found by googling and installed
manually in the C{~/texmf/tex/latex/misc} directory).
The I{minted} LaTeX style is offered by C{ptex2tex} and popular among
users. This style requires the package U{Pygments<a href="http://pygments.org">http://pygments.org<a href="http://pygments.org">http://pygments.org</a>}::
        hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
        cd pygments
        sudo python setup.py install
If you use the minted style, you have to enable it by running
C{ptex2tex -DMINTED} and then C{latex -shell-escape}, see
the the section "From Doconce to Other Formats".
For C{rst} output and further transformation to LaTeX, HTML, XML,
OpenOffice, and so on, one needs U{docutils<http://docutils.sourceforge.net>}.
The installation can be done by::
        svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/
docutils
        cd docutils
        sudo python setup.py install
        cd ..
To use the OpenOffice suite you will typically on Debian systems install::
        sudo apt-get install unovonv libreoffice libreoffice-dmaths
There is a possibility to create PDF files from reST documents
using ReportLab instead of LaTeX. The enabling software is
U{rst2pdf<http://code.google.com/p/rst2pdf>}. Either download the tarball
```

```
tutorial.epytext
or clone the svn repository, go to the C{rst2pdf} directory and
run C{sudo python setup.py install}.
Output to C{sphinx} requires of course U{Sphinx<http://sphinx.pocoo.org>},
installed by::
        hg clone https://bitbucket.org/birkenfeld/sphinx
        cd sphinx
        sudo python setup.py install
        cd ..
When the output format is C{epydoc} one needs that program too, installed
by::
        svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc ep
ydoc
        cd epydoc
        sudo make install
        cd ..
Finally, translation to C{pandoc} requires the
U{Pandoc<http://johnmacfarlane.net/pandoc/>} program
(written in Haskell) to be installed::
        sudo apt-get install pandoc
I{Remark.} Several of the packages above installed from source code
are also available in Debian-based system through the
C{apt-get install} command. However, we recommend installation directly
from the version control system repository as there might be important
updates and bug fixes. For C{svn} directories, go to the directory,
run C{svn update}, and then C{sudo python setup.py install}. For
Mercurial (C{hg}) directories, go to the directory, run
C{hg pull; hg update}, and then C{sudo python setup.py install}.
Doconce itself is frequently updated so these commands should be
run regularly.
```

"

#summary Doconce: Document Once, Include Anywhere
<wiki:toc max\_depth="2" />
By \*Hans Petter Langtangen\*

==== Mar 11, 2012 ====

- \* When writing a note, report, manual, etc., do you find it difficult to choo se the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- ly go with a particular format?

  \* Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like [http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf LaTeX], [http://www.htmlcodet utorial.com/ HTML], [http://docutils.sourceforge.net/docs/ref/rst/restructuredte xt.html reStructuredText], [http://sphinx.pocoo.org/contents.html Sphinx], and [http://code.google.com/p/support/wiki/WikiSyntax wiki]? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- \* Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

== The Doconce Concept ==

Doconce is two things:

# Doconce is a very simple and minimally tagged markup language that looks l ike ordinary ASCII text (much like what you would use in an email), but the t ext can be transformed to numerous other formats, including HTML, Pandoc, Goo gle wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plai formatting/tags are removed for clear reading in, e n text (where non-obvious emails). From reST you can (via 'rst2\*' programs) go to XML, HTML, TeX, PDF, OpenOffice, and from the latter (via 'unoconv') to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. Markdown, reST, LaTeX, HTML, PDF, DocBook XML, From Pandoc one can generate Texinfo, MediaWiki, RTF, Groff, and other formats. OpenOffice, GNU

# Doconce is a working strategy for never duplicating information. Text is w
ritten in a single place and then transformed to a number of different destin
ations of diverse type (software source code, manuals, tutorials, books, wiki
s, memos, emails, etc.). The Doconce markup language support this working str
ategy. The slogan is: "Write once, include anywhere".

Here are some Doconce features:

- \* Doconce markup does include tags, so the format is more tagged than Markd own and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- \* Doconce can be converted to plain \*untagged\* text, often desirable for computer programs and email.
- \* Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files.
  - \* Doconce has full support for LaTeX math, and integrates very well with bi

g LaTeX projects (books).

- \* Doconce is almost self-explanatory and is a handy starting point for gene rating documents in more complicated markup languages, such as Google wiki, L aTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- \* Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is ob viously a superior tool.

Doconce was particularly written for the following sample applications:

- \* Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- \* Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for u se with Sphinx, as wiki text when publishing the software at web sites, and a s LaTeX integrated in, e.g., a thesis.
- \* Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

== What Does Doconce Look Like? ==

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- \* Bullet lists arise from lines starting with an asterisk.
- \* \*Emphasized words\* are surrounded by asterisks.
- \* \*Words in boldface\* are surrounded by underscores.
- \* Words from computer code are enclosed in back quotes and then typeset 've rbatim (in a monospace font)'.
- \* Section headings are recognied by equality ('=') signs before and after the title, and the number of '=' signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
  - \* Paragraph headings are recognized by a double underscore before and after the heading.
  - \* The abstract of a document starts with \*Abstract\* as paragraph heading, a

nd all text up to the next heading makes up the abstract,

- \* Blocks of computer code can easily be included by placing '!bc' (begin co de) and '!ec' (end code) commands at separate lines before and after the code block.
  - \* Blocks of computer code can also be imported from source files.
- \* Blocks of LaTeX mathematics can easily be included by placing '!bt' (begin TeX) and '!et' (end TeX) commands at separate lines before and after the math block.
  - \* There is support for both LaTeX and text-like inline mathematics.
- \* Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- \* Invisible comments in the output format can be inserted throughout the text.
- \* Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
  - \* There is special support for advanced exercises features.
- \* With a simple preprocessor, Preprocess or Mako, one can include other doc uments (files) and large portions of text can be defined in or out of the text.
  - \* With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time | velocity | acceleration

```
tutorial.gwiki
    0.0
           1.4186
                      -5.01
    2.0
           1.376512
                      11.919
    4.0
          1.1E + 1
                    | 14.717624
# lines beginning with # are comment lines
The Doconce text above results in the following little document:
==== A Subsection with Sample Text ====
Ordinary text looks like ordinary text, and the tags used for
*boldface* words, *emphasized* words, and 'computer' words look
natural in plain text. Lists are typeset as you would do in an email,
  * item 1
  * item 2
  * item 3
Lists can also have numbered items instead of bullets, just use an 'o'
(for ordered) instead of the asterisk:
 # item 1
 # item 2
 # item 3
URLs with a link word are possible, as in [http://folk.uio.no/hpl hpl].
If the word is URL, the URL itself becomes the link name,
as in tutorial.do.txt.
References to sections may use logical names as labels (e.g., a
"label" command right after the section title), as in the reference to
the section [#A_Subsection_with_Sample_Text].
Doconce also allows inline comments such as [hpl: here I will make
some remarks to the text] for allowing authors to make notes. Inline
comments can be removed from the output by a command-line argument
(see the section [#From Doconce to Other Formats] for an example).
Tables are also supperted, e.g.,
         *time*
                                                *acceleration*
                            *velocity*
     0.0
                          1.4186
                                               -5.01
     2.0
                          1.376512
                                               11.919
                                               14.717624
     4.0
                          1.1E + 1
==== Mathematics and Computer Code ====
Inline mathematics, such as v = \sin(x),
allows the formula to be specified both as LaTeX and as plain text.
This results in a professional LaTeX typesetting, but in other formats
the text version normally looks better than raw LaTeX mathematics with
backslashes. An inline formula like v = \sin(x) is
typeset as
{ { {
\ln = \sin(x) v = \sin(x)
```

```
tutorial.gwiki
} } }
The pipe symbol acts as a delimiter between LaTeX code and the plain text
version of the formula.
Blocks of mathematics are better typeset with raw LaTeX, inside
'!bt' and '!et' (begin tex / end tex) instructions.
The result looks like this:
{ { {
\begin{eqnarray}
{\partial u\over\partial t} &=& \nabla^2 u + f, label{myeq1}\\
{\partial v\over\partial t} &=& \nabla\cdot(q(u)\nabla v) + g
\end{eqnarray}
Of course, such blocks only looks nice in LaTeX. The raw
LaTeX syntax appears in all other formats (but can still be useful
for those who can read LaTeX syntax).
You can have blocks of computer code, starting and ending with
'!bc' and '!ec' instructions, respectively. Such blocks look like
{ { {
from math import sin, pi
def myfunc(x):
    return sin(pi*x)
import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
} } }
A code block must come after some plain sentence (at least for successful
output to 'sphinx', 'rst', and ASCII-close formats),
not directly after a section/paragraph heading or a table.
It is possible to add a specification of an
environment for typesetting the verbatim code block, e.g., '!bc xxx'
where 'xxx' is an identifier like 'pycod' for code snippet in Python,
'sys' for terminal session, etc. When Doconce is filtered to LaTeX,
these identifiers are used as in 'ptex2tex' and defined in a
configuration file '.ptext2tex.cfg', while when filtering
to Sphinx, one can have a comment line in the Doconce file for
mapping the identifiers to legal language names for Sphinx (which equals
the legal language names for Pygments):
# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console
By default, 'pro' and 'cod' are 'python', 'sys' is 'console', while 'xpro' and 'xcod' are computer language specific for 'x'
in 'f' (Fortran), 'c' (C), 'cpp' (C++), 'pl' (Perl), 'm' (Matlab),
'sh' (Unix shells), 'cy' (Cython), and 'py' (Python).
<wiki:comment> (Any sphinx code-block comment, whether inside verbatim code </wi
<wiki:comment> blocks or outside, yields a mapping between bc arguments </wiki:c</pre>
<wiki:comment> and computer languages. In case of muliple definitions, the </wik</pre>
i:comment>
<wiki:comment> first one is used.) </wiki:comment>
One can also copy computer code directly from files, either the
complete file or specified parts. Computer code is then never
duplicated in the documentation (important for the principle of
```

avoiding copying information!). A complete file is typeset with '!bc pro', while a part of a file is copied into a '!bc cod' environment. What 'pro' and 'cod' mean is then defined through a '.ptex2tex.cfg' file for LaTeX and a 'sphinx code-blocks' comment for Sphinx.

Another document can be included by writing '#include "mynote.do.txt"' on a line starting with (another) hash sign. Doconce documents have extension 'do.txt'. The 'do' part stands for doconce, while the trailing '.txt' denotes a text document so that editors gives you the right writing environment for plain text.

==== Macros (Newcommands), Cross-References, Index, and Bibliography ====

Doconce supports a type of macros via a LaTeX-style \*newcommand\* construction. The newcommands defined in a file with name 'newcommand\_replace.tex' are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion Newcommands in files with names 'newcommands.tex' and 'newcommands\_keep.tex' are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by '!bt' and '!et' in 'newcommands\_keep.tex' to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in 'newcommands\_replace.tex' and expanded by Doconce. The definitions of newcommands in the 'newcommands\*.tex' files \*must\* appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the 'doc/manual/manual.do.txt' file (see the [https://doconce.googlecode.com/hg/doc/demos/manual/index.html demo page] for various formats of this document).

<wiki:comment> Example on including another Doconce file (using preprocess): </wi>

== From Doconce to Other Formats ==

Transformation of a Doconce document 'mydoc.do.txt' to various other formats applies the script 'doconce format':  $\{\{\{Terminal> doconce format format mydoc.do.txt\}\}\}$ 

```
tutorial.gwiki
or just
{ { {
Terminal> doconce format format mydoc
The 'mako' or 'preprocess' programs are always used to preprocess the
file first, and options to 'mako' or 'preprocess' can be added after the
filename. For example,
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5
                                                                              # preprocess
Terminal> doconce format latex yourdoc extra_sections=True VAR1=5 # make
The variable 'FORMAT' is always defined as the current format when running 'preprocess'. That is, in the last example, 'FORMAT' is defined as 'latex'. Inside the Doconce document one can then perform
format specific actions through tests like '#if FORMAT == "latex" .
Inline comments in the text are removed from the output by
{ { {
Terminal > doconce format latex mydoc --skip_inline_comments
One can also remove all such comments from the original Doconce
file by running:
Terminal > doconce remove inline comments mydoc
This action is convenient when a Doconce document reaches its final form
and comments by different authors should be removed.
==== HTML ====
Making an HTML version of a Doconce file 'mydoc.do.txt'
is performed by
{ { {
Terminal > doconce format html mydoc
The resulting file 'mydoc.html' can be loaded into any web browser for viewing.
==== Pandoc ====
Output in the versatile Pandoc format results from
Terminal > doconce format pandoc mydoc
The name of the output file is 'mydoc.pnd'.
From this format one can go to numerous other formats:
Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd
Terminal> pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd
}}}
Pandoc supports 'latex', 'html', 'odt' (OpenOffice), 'docx' (Microsoft Word), 'rtf', 'texinfo', to mention some. The '-R' option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it.
See the [http://johnmacfarlane.net/pandoc/README.html Pandoc documentation]
for the many features of the 'pandoc' program.
==== LaTeX ====
Making a LaTeX file 'mydoc.tex' from 'mydoc.do.txt' is done in two steps:
<wiki:comment> Note: putting code blocks inside a list is not successful in many
```

```
tutorial.gwiki
 </wiki:comment>
<wiki:comment> formats - the text may be messed up. A better choice is a paragra
ph </wiki:comment>
<wiki:comment> environment, as used here. </wiki:comment>
*Step 1.* Filter the doconce text to a pre-LaTeX form 'mydoc.p.tex' for
      'ptex2tex':
Terminal> doconce format latex mydoc
} } }
LaTeX-specific commands ("newcommands") in math formulas and similar
can be placed in files 'newcommands.tex', 'newcommands_keep.tex', or
'newcommands_replace.tex' (see the section [#Macros_(Newcommands),_Cross-Referen
ces,_Index,_and_Bibliography]).
If these files are present, they are included in the LaTeX document
so that your commands are defined.
*Step 2.* Run 'ptex2tex' (if you have it) to make a standard LaTeX file,
Terminal> ptex2tex mydoc
}}}
or just perform a plain copy,
{{{
Terminal > cp mydoc.p.tex mydoc.tex
Doconce generates a '.p.tex' file with some preprocessor macros
that can be used to steer certain properties of the LaTeX document.
For example, to turn on the Helvetica font instead of the standard
Computer Modern font, run
{ { {
Terminal> ptex2tex -DHELVETICA mydoc
} } }
The title, authors, and date are by default typeset in a non-standard
way to enable a nicer treatment of multiple authors having
institutions in common. However, the standard LaTeX "maketitle" heading
is also available through
{ { {
Terminal> ptex2tex -DLATEX_HEADING=traditional mydoc
A separate titlepage can be generate by
Terminal> ptex2tex -DLATEX_HEADING=titlepage mydoc
}}}
The 'ptex2tex' tool makes it possible to easily switch between many
different fancy formattings of computer or verbatim code in LaTeX
documents. After any '!bc' command in the Doconce source you can insert verbatim block styles as defined in your '.ptex2tex.cfg' file, e.g., '!bc cod' for a code snippet, where 'cod' is set to a certain environment in '.ptex2tex.cfg' (e.g., 'CodeIntended').
There are over 30 styles to choose from.
*Step 2b (optional).* Edit the 'mydoc.tex' file to your needs.
For example, you may want to substitute 'section' by 'section' to
avoid numbering of sections, you may want to insert linebreaks
(and perhaps space) in the title, etc. This can be automatically
edited with the aid of the 'doconce replace' and 'doconce subst'
commands. The former works with substituting text directly, while the
latter performs substitutions using regular expressions.
```

```
tutorial.gwiki
Here are some examples:
Terminal> doconce replace 'section{' 'section*{' mydoc.tex
Terminal> doconce subst 'title\{(.+)Using (.+)\}' \
          'title{\g<1> \\\ [1.5mm] Using \g<2>' mydoc.tex
A lot of tailored fixes to the LaTeX document can be done by
an appropriate set of text replacements and regular expression
substitutions. You are anyway encourged to make a script for
generating PDF from the LaTeX file.
*Step 3.* Compile 'mydoc.tex'
and create the PDF file:
{ { {
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc
                          # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
If one wishes to use the 'Minted_Python', 'Minted_Cpp', etc.,
environments in 'ptex2tex' for typesetting code (specified, e.g., in
the '*pro' and '*cod' environments in '.ptex2tex.cfg' or
'$HOME/.ptex2tex.cfg'), the 'minted' LaTeX package is needed. This
package is included by running 'doconce format' with the '-DMINTED'
option:
{ { {
Terminal> ptex2tex -DMINTED mydoc
In this case, 'latex' must be run with the
'-shell-escape' option:
{ { {
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
}}}
==== PDFLaTeX ====
Running 'pdflatex' instead of 'latex' follows almost the same steps,
but the start is
{ { {
Terminal > doconce format latex mydoc
}}}
Then 'ptex2tex' is run as explained above, and finally
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc # if bibliography
Terminal> pdflatex -shell-escape mydoc
} } }
==== Plain ASCII Text ====
We can go from Doconce "back to" plain untagged text suitable for viewing
```

```
tutorial.gwiki
in terminal windows, inclusion in email text, or for insertion in
computer source code:
{ { {
Terminal > doconce format plain mydoc.do.txt # results in mydoc.txt
} } }
==== reStructuredText ====
Going from Doconce to reStructuredText gives a lot of possibilities to
go to other formats. First we filter the Doconce text to a
reStructuredText file 'mydoc.rst':
Terminal > doconce format rst mydoc.do.txt
} } }
We may now produce various other formats:
{ { {
Terminal > rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py
                       mydoc.rst > mydoc.odt # OpenOffice
}}}
The OpenOffice file 'mydoc.odt' can be loaded into OpenOffice and
saved in, among other things, the RTF format or the Microsoft Word format.
However, it is more convenient to use the program 'unovonv'
to convert between the many formats OpenOffice supports *on the command line*.
Run
{ { {
Terminal> unoconv --show
} } }
to see all the formats that are supported.
For example, the following commands take
'mydoc.odt' to Microsoft Office Open XML format,
classic MS Word format, and PDF:
{ { {
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
}}}
*Remark about Mathematical Typesetting.* At the time of this writing, there is n
o easy way to go from Doconce
and LaTeX mathematics to reST and further to OpenOffice and the
"MS Word world". Mathematics is only fully supported by 'latex' as
output and to a wide extent also supported by the 'sphinx' output format.
Some links for going from LaTeX to Word are listed below.
 * http://ubuntuforums.org/showthread.php?t=1033441
 * http://tug.org/utilities/texconv/textopc.html
 * http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html
==== Sphinx ====
Sphinx documents demand quite some steps in their creation. We have automated
most of the steps through the 'doconce sphinx_dir' command:
Terminal> doconce sphinx_dir author="authors' names" \
          title="some title" version=1.0 dirname=sphinxdir \
```

```
tutorial.gwiki
           theme=mytheme file1 file2 file3 ...
The keywords 'author', 'title', and 'version' are used in the headings
of the Sphinx document. By default, 'version' is 1.0 and the script
will try to deduce authors and title from the doconce files 'filel',
'file2', etc. that together represent the whole document. Note that
none of the individual Doconce files 'file1', 'file2', etc. should
include the rest as their union makes up the whole document.
The default value of 'dirname' is 'sphinx-rootdir'. The 'theme'
keyword is used to set the theme for design of HTML output from
Sphinx (the default theme is ''default'').
With a single-file document in 'mydoc.do.txt' one often just runs
Terminal > doconce sphinx_dir mydoc
} } }
and then an appropriate Sphinx directory 'sphinx-rootdir' is made with
relevant files.
The 'doconce sphinx_dir' command generates a script
'automake-sphinx.py' for compiling the Sphinx document into an HTML
document. One can either run 'automake-sphinx.py' or perform the
steps in the script manually, possibly with necessary modifications.
You should at least read the script prior to executing it to have
some idea of what is done.
Te 'doconce sphinx_dir' script copies directories named 'figs' or 'figures'
over to the Sphinx directory so that figures are accessible in the
Sphinx compilation. If figures or movies are located in other
directories, 'automake-sphinx.py' must be edited accordingly.

Links to local files (not 'http:' or 'file:' URLs) must be placed in the '_static' subdirectory of the Sphinx directory. The utility 'doconce sphinxfix_localURLs' is run to check for local
links: for each such link, say 'dir1/dir2/myfile.txt' it replaces
the link by '_static/myfile.txt' and copies 'dir1/dir2/myfile.txt'
to a local '_static' directory (in the same directory as the
script is run). The user must copy all '_static/*' files to the
'_static' subdirectory of the Sphinx directory. Links to local
HTML files (say another Sphinx document) may present a problem if they link
to other files: all necessary files must be correctly copied to
the 'static' subdirectory of the Sphinx directory.
It may be wise to place relevant files in a '_static' directory
and link to these directly from the Doconce document - then links
to not need to be modified when creating a Sphinx version of
the document.
Doconce comes with a collection of HTML themes for Sphinx documents.
These are packed out in the Sphinx directory, the 'conf.py'
configuration file for Sphinx is edited accordingly, and a script
'make-themes.sh' can make HTML documents with one or more themes.
For example,
to realize the themes 'fenics' and 'pyramid', one writes
{{{
Terminal> ./make-themes.sh fenics pyramid
The resulting directories with HTML documents are '_build/html_fenics'
and '_build/html_pyramid', respectively. Without arguments,
'make-themes.sh' makes all available themes (!).
```

```
tutorial.gwiki
If it is not desirable to use the autogenerated scripts explained
above, here is the complete manual procedure of generating a
Sphinx document from a file 'mydoc.do.txt'.
*Step 1.* Translate Doconce into the Sphinx format:
Terminal > doconce format sphinx mydoc
} } }
*Step 2.* Create a Sphinx root directory
either manually or by using the interactive 'sphinx-quickstart'
program. Here is a scripted version of the steps with the latter:
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
Name of My Sphinx Document
Author
version
version
.rst
index
n
У
n
n
n
n
У
n
n
У
У
У
EOF
} } }
The autogenerated 'conf.py' file
may need some edits if you want to specific layout (Sphinx themes)
of HTML pages. The 'doconce sphinx dir' generator makes an extended 'conv.py'
file where, among other things, several useful Sphinx extensions
are included.
*Step 3.* Copy the 'mydoc.rst' file to the Sphinx root directory:
{ { {
Terminal> cp mydoc.rst sphinx-rootdir
If you have figures in your document, the relative paths to those will
be invalid when you work with 'mydoc.rst' in the 'sphinx-rootdir'
directory. Either edit 'mydoc.rst' so that figure file paths are correct,
or simply copy your figure directories to 'sphinx-rootdir'. Links to local files in 'mydoc.rst' must be modified to links to
files in the '_static' directory, see comment above.
*Step 4.* Edit the generated 'index.rst' file so that 'mydoc.rst'
is included, i.e., add 'mydoc' to the 'toctree' section so that it becomes
{ { {
```

```
tutorial.gwiki
.. toctree::
   :maxdepth: 2
   mydoc
}}}
(The spaces before 'mydoc' are important!)
*Step 5.* Generate, for instance, an HTML version of the Sphinx source:
make clean
             # remove old versions
make html
}}}
Sphinx can generate a range of different formats:
standalone HTML, HTML in separate directories with 'index.html' files,
a large single HTML file, JSON files, various help files (the qthelp, HTML,
and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages,
and Texinfo files.
*Step 6.* View the result:
Terminal> firefox _build/html/index.html
} } }
Note that verbatim code blocks can be typeset in a variety of ways
depending the argument that follows '!bc': 'cod' gives Python
('code-block: python' in Sphinx syntax) and 'cppcod' gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.
==== Google Code Wiki ====
There are several different wiki dialects, but Doconce only support the
one used by [http://code.google.com/p/support/wiki/WikiSyntax Google Code].
The transformation to this format, called 'gwiki' to explicitly mark
it as the Google Code dialect, is done by
Terminal > doconce format gwiki mydoc.do.txt
You can then open a new wiki page for your Google Code project, copy
the 'mydoc.qwiki' output file from 'doconce format' and paste the
file contents into the wiki page. Press *Preview* or *Save Page* to
see the formatted result.
When the Doconce file contains figures, each figure filename must be
replaced by a URL where the figure is available. There are instructions
in the file for doing this. Usually, one performs this substitution
automatically (see next section).
==== Tweaking the Doconce Output ====
Occasionally, one would like to tweak the output in a certain format
from Doconce. One example is figure filenames when transforming
Doconce to reStructuredText. Since Doconce does not know if the
'.rst' file is going to be filtered to LaTeX or HTML, it cannot know
if '.eps' or '.png' is the most appropriate image filename.
The solution is to use a text substitution command or code with, e.g., sed,
perl, python, or scitools subst, to automatically edit the output file
from Doconce. It is then wise to run Doconce and the editing commands
from a script to automate all steps in going from Doconce to the final
```

```
tutorial.gwiki
format(s). The 'make.sh' files in 'docs/manual' and 'docs/tutorial'
constitute comprehensive examples on how such scripts can be made.
==== Demos ====
The current text is generated from a Doconce format stored in the file
docs/tutorial/tutorial.do.txt
} } }
The file 'make.sh' in the 'tutorial' directory of the
Doconce source code contains a demo of how to produce a variety of
formats. The source of this tutorial, 'tutorial.do.txt' is the starting point. Running 'make.sh' and studying the various generated files and comparing them with the original 'tutorial.do.txt' file,
gives a quick introduction to how Doconce is used in a real case.
[https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html Here]
is a sample of how this tutorial looks in different formats.
There is another demo in the 'docs/manual' directory which
translates the more comprehensive documentation, 'manual.do.txt', to
various formats. The 'make.sh' script runs a set of translations.
==== Dependencies and Installation ====
Doconce itself is pure Python code hosted at http://code.google.com/p/doconce.
Its installation from the
Mercurial ('hg') source follows the standard procedure:
{ { {
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
} } }
If you make use of the [http://code.google.com/p/preprocess Preprocess]
preprocessor, this program must be installed:
{{{
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
cd ..
A much more advanced alternative to Preprocess is
[http://www.makotemplates.org Mako]. Its installation is most
conveniently done by 'pip',
{ { {
pip install Mako
}}}
This command requires 'pip' to be installed. On Debian Linux systems,
such as Ubuntu, the installation is simply done by
{{{
sudo apt-get install python-pip
} } }
Alternatively, one can install from the 'pip' [http://pypi.python.org/pypi/pip s
ource code].
To make LaTeX
```

```
tutorial.gwiki
documents (without going through the reStructuredText format) you
need [http://code.google.com/p/ptex2tex ptex2tex], which is
installed by
{{{
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
} } }
As seen, 'cp2texmf.sh' copies some special stylefiles that
that 'ptex2tex' potentially makes use of. Some more standard stylefiles are also needed. These are installed by
sudo apt-get install texlive-latex-extra
}}}
on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with
the necessary stylefiles (if not, they can be found by googling and installed
manually in the '~/texmf/tex/latex/misc' directory).
The *minted* LaTeX style is offered by 'ptex2tex' and popular among
users. This style requires the package [http://pygments.org Pygments]:
{ { {
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
if you use the minted style, you have to enable it by running
'ptex2tex -DMINTED' and then 'latex -shell-escape', see
the the section [#From Doconce to Other Formats].
For 'rst' output and further transformation to LaTeX, HTML, XML,
OpenOffice, and so on, one needs [http://docutils.sourceforge.net docutils].
The installation can be done by
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
cd docutils
sudo python setup.py install
cd ..
}}}
To use the OpenOffice suite you will typically on Debian systems install
{ { {
sudo apt-get install unovonv libreoffice libreoffice-dmaths
} } }
There is a possibility to create PDF files from reST documents
using ReportLab instead of LaTeX. The enabling software is [http://code.google.com/p/rst2pdf rst2pdf]. Either download the tarball
or clone the svn repository, go to the 'rst2pdf' directory and
run 'sudo python setup.py install'.
Output to 'sphinx' requires of course [http://sphinx.pocoo.org Sphinx],
installed by
{{{
hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
```

```
tutorial.gwiki
cd ..
} } }
When the output format is 'epydoc' one needs that program too, installed
} }
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ..
} } }
Finally, translation to 'pandoc' requires the
[http://johnmacfarlane.net/pandoc/ Pandoc] program
(written in Haskell) to be installed.
{ { {
sudo apt-get install pandoc
} } }
*Remark.* Several of the packages above installed from source code
are also available in Debian-based system through the
'apt-get install' command. However, we recommend installation directly
from the version control system repository as there might be important
updates and bug fixes. For 'svn' directories, go to the directory, run 'svn update', and then 'sudo python setup.py install'. For Mercurial ('hg') directories, go to the directory, run
'hg pull; hg update', and then 'sudo python setup.py install'.
Doconce itself is frequently updated so these commands should be
run regularly.
```

- % Doconce: Document Once, Include Anywhere
- % Hans Petter Langtangen at Simula Research Laboratory and University of Oslo
- % Mar 11, 2012
  - \* When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- \* Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like [LaTeX](http://refcards.com/docs/silvermanj/amslatex/LaTeXRefCard.v2.0.pdf), [HTML](http://www.htmlcodetutorial.com/), [reStructuredText](http://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html), [Sphinx](http://sphinx.pocoo.org/contents.html), and [wiki](http://code.google.com/p/support/wiki/WikiSyntax)? Would it be convenient

to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?

\* Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

# The Doconce Concept

#### Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via 'rst2\*' programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via 'unoconv') to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

#### Here are some Doconce features:

\* Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than

LaTeX and HTML.

- \* Doconce can be converted to plain \*untagged\* text, often desirable for computer programs and email.
- \* Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files.
- \* Doconce has full support for LaTeX math, and integrates very well with big LaTeX projects (books).
- \* Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make the initial versions of a Sphinx or wiki document.
- \* Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is obviously a superior tool.

Doconce was particularly written for the following sample applications:

- \* Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- \* Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- \* Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

## What Does Doconce Look Like?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- \* Bullet lists arise from lines starting with an asterisk.
- \* \*Emphasized words\* are surrounded by asterisks.
- \* Words in boldface are surrounded by underscores.
- \* Words from computer code are enclosed in back quotes and then typeset 'verbatim (in a monospace font)'.
- \* Section headings are recognied by equality ('=') signs before and after the title, and the number of '=' signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- \* Paragraph headings are recognized by a double underscore before and after the heading.
- \* The abstract of a document starts with \*Abstract\* as paragraph heading, and all text up to the next heading makes up the abstract,
- \* Blocks of computer code can easily be included by placing '!bc' (begin code) and '!ec' (end code) commands at separate lines before and after the code block.
- \* Blocks of computer code can also be imported from source files.
- \* Blocks of LaTeX mathematics can easily be included by placing '!bt' (begin TeX) and '!et' (end TeX) commands at separate lines before and after the math block.
- \* There is support for both LaTeX and text-like inline mathematics.
- \* Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- \* Invisible comments in the output format can be inserted throughout the text.
- \* Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- \* There is special support for advanced exercises features.
- \* With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- \* With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

==== A Subsection with Sample Text ==== label{my:first:sec}

Ordinary text looks like ordinary text, and the tags used for

\_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2
- o item 3

URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl". If the word is URL, the URL itself becomes the link name, as in "URL": "tutorial.do.txt".

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
r	r	r
0.0	1.4186	-5.01
2.0	1.376512	11.919
4.0	1.1E+1	14.717624
	' 	

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for \_boldface\_ words, \*emphasized\* words, and 'computer' words look natural in plain text. Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have numbered items instead of bullets, just use an 'o' (for ordered) instead of the asterisk:

1. item 1

- 2. item 2
- 3. item 3

URLs with a link word are possible, as in [hpl](http://folk.uio.no/hpl). If the word is URL, the URL itself becomes the link name, as in <tutorial.do.txt>.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section [A Subsection with Sample Text](#t).

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section [From Doconce to Other Formats](#s) for an example).

Tables are also supperted, e.g.,

time	velocity	acceleration
0.0	1.4186	-5.01
2.0 4.0	1.376512 1.1E+1	11.919 14.717624

Mathematics and Computer Code

Inline mathematics, such as  $nu = \sin(x)$ , allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like  $nu = \sin(x)$  is typeset as

```
 \begin{cases} \text{yu} = \sin(x) \\ \text{y} = \sin(x) \end{cases}
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula.

Blocks of mathematics are better typeset with raw LaTeX, inside '!bt' and '!et' (begin tex / end tex) instructions.
The result looks like this:

```
\begin{eqnarray}
{\partial u\over\partial t} &=& \nabla^2 u + f, label{myeq1}\\
{\partial v\over\partial t} &=& \nabla\cdot(q(u)\nabla v) + g
\end{eqnarray}
```

Of course, such blocks only looks nice in LaTeX. The raw LaTeX syntax appears in all other formats (but can still be useful for those who can read LaTeX syntax).

You can have blocks of computer code, starting and ending with '!bc' and '!ec' instructions, respectively. Such blocks look like

-----{.Python}

from math import sin, pi
def myfunc(x):
 return sin(pi\*x)

import integrate

I = integrate.trapezoidal(myfunc, 0, pi, 100)

A code block must come after some plain sentence (at least for successful output to 'sphinx', 'rst', and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., '!bc xxx' where 'xxx' is an identifier like 'pycod' for code snippet in Python, 'sys' for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in 'ptex2tex' and defined in a configuration file '.ptext2tex.cfg', while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

By default, 'pro' and 'cod' are 'python', 'sys' is 'console', while 'xpro' and 'xcod' are computer language specific for 'x' in 'f' (Fortran), 'c' (C), 'cpp' (C++), 'pl' (Perl), 'm' (Matlab), 'sh' (Unix shells), 'cy' (Cython), and 'py' (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with '!bc pro', while a part of a file is copied into a '!bc cod' environment. What 'pro' and 'cod' mean is then defined through a '.ptex2tex.cfg' file for LaTeX and a 'sphinx code-blocks' comment for Sphinx.

Another document can be included by writing '#include "mynote.do.txt"' on a line starting with (another) hash sign. Doconce documents have extension 'do.txt'. The 'do' part stands for doconce, while the trailing '.txt' denotes a text document so that editors gives you the right writing environment for plain text.

Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style \*newcommand\* construction. The newcommands defined in a file with name 'newcommand\_replace.tex' are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion

itself). Newcommands in files with names 'newcommands.tex' and 'newcommands\_keep.tex' are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by '!bt' and '!et' in 'newcommands\_keep.tex' to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in 'newcommands\_replace.tex' and expanded by Doconce. The definitions of newcommands in the 'newcommands\*.tex' files \*must\* appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the 'doc/manual/manual.do.txt' file (see the [demo page](https://doconce.googlecode.com/hg/doc/demos/manual/index.html) for various formats of this document).

# From Doconce to Other Formats

Transformation of a Doconce document 'mydoc.do.txt' to various other formats applies the script 'doconce format':

-----{.Bash}
Terminal> doconce format format mydoc.do.txt

or just

-----{.Bash}

Terminal> doconce format format mydoc

The 'mako' or 'preprocess' programs are always used to preprocess the file first, and options to 'mako' or 'preprocess' can be added after the filename. For example,

-----{.Bash}
Terminal> doconce format latex mydoc -Dextra sections -DVAR1=5 # r

Terminal> doconce format latex mydoc -Dextra\_sections -DVAR1=5 # preprocess Terminal> doconce format latex yourdoc extra\_sections=True VAR1=5 # mako

The variable 'FORMAT' is always defined as the current format when running 'preprocess'. That is, in the last example, 'FORMAT' is defined as 'latex'. Inside the Doconce document one can then perform

```
tutorial.pnd
format specific actions through tests like '#if FORMAT == "latex"'.
Inline comments in the text are removed from the output by
~~~~~~~~~~~~~~~~~{.Bash}
Terminal> doconce format latex mydoc --skip_inline_comments
One can also remove all such comments from the original Doconce
file by running:
Terminal > doconce remove_inline_comments mydoc
This action is convenient when a Doconce document reaches its final form
and comments by different authors should be removed.
HTML
Making an HTML version of a Doconce file 'mydoc.do.txt'
is performed by
~~~~~~~~~~~~~~~~~{.Bash}
Terminal > doconce format html mydoc
The resulting file 'mydoc.html' can be loaded into any web browser for viewing.
Pandoc
Output in the versatile Pandoc format results from
~~~~~~~~~~~~~~~~~{.Bash}
Terminal > doconce format pandoc mydoc
The name of the output file is 'mydoc.pnd'.
From this format one can go to numerous other formats:
-----{.Bash}
Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd
Terminal > pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd
Pandoc supports 'latex', 'html', 'odt' (OpenOffice), 'docx' (Microsoft Word), 'rtf', 'texinfo', to mention some. The '-R' option makes
Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it.
See the [Pandoc documentation](http://johnmacfarlane.net/pandoc/README.html)
for the many features of the 'pandoc' program.
LaTeX
Making a LaTeX file 'mydoc.tex' from 'mydoc.do.txt' is done in two steps:
```

" tutorial.pnd "
*Step 1.* Filter the doconce text to a pre-LaTeX form 'mydoc.p.tex' for 'ptex2tex':
Terminal> doconce format latex mydoc
LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files 'newcommands.tex', 'newcommands_keep.tex', or 'newcommands_replace.tex' (see the section [Macros (Newcommands), Cross-References, Index, and Bibliography](#y)). If these files are present, they are included in the LaTeX document so that your commands are defined.
*Step 2.* Run 'ptex2tex' (if you have it) to make a standard LaTeX file,
Terminal> ptex2tex mydoc
or just perform a plain copy,
Terminal> cp mydoc.p.tex mydoc.tex
Doconce generates a '.p.tex' file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run
Terminal> ptex2tex -DHELVETICA mydoc
The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through
~~~~~~{.Bash} Terminal> ptex2tex -DLATEX_HEADING=traditional mydoc
A separate titlepage can be generate by
<pre>~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~</pre>
The 'ptex2tex' tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any '!bc' command in the Doconce source you can insert verbatim block styles as defined in your '.ptex2tex.cfg' file, e.g., '!bc cod' for a code snippet, where 'cod' is set to a certain environment in '.ptex2tex.cfg' (e.g., 'CodeIntended'). There are over 30 styles to choose from.

```
tutorial.pnd
*Step 2b (optional).* Edit the 'mydoc.tex' file to your needs.
For example, you may want to substitute 'section' by 'section' to
avoid numbering of sections, you may want to insert linebreaks
(and perhaps space) in the title, etc. This can be automatically
edited with the aid of the 'doconce replace' and 'doconce subst'
commands. The former works with substituting text directly, while the
latter performs substitutions using regular expressions.
Here are some examples:
~~~~~~~~{.Bash}
A lot of tailored fixes to the LaTeX document can be done by
an appropriate set of text replacements and regular expression
substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.
*Step 3.* Compile 'mydoc.tex'
and create the PDF file:
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal > latex mydoc
Terminal > dvipdf mydoc
If one wishes to use the 'Minted_Python', 'Minted_Cpp', etc.,
environments in 'ptex2tex' for typesetting code (specified, e.g., in
the '*pro' and '*cod' environments in '.ptex2tex.cfg' or
'$HOME/.ptex2tex.cfg'), the 'minted' LaTeX package is needed. This
package is included by running 'doconce format' with the '-DMINTED'
option:
-----{.Bash}
Terminal> ptex2tex -DMINTED mydoc
In this case, 'latex' must be run with the
'-shell-escape' option:
-----{.Bash}
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
PDFLaTeX
```

" tutorial.pnd "
Running 'pdflatex' instead of 'latex' follows almost the same steps, but the start is
Terminal> doconce format latex mydoc
Then 'ptex2tex' is run as explained above, and finally
Terminal> pdflatex -shell-escape mydoc Terminal> makeindex mydoc # if index Terminal> bibitem mydoc # if bibliography Terminal> pdflatex -shell-escape mydoc
Plain ASCII Text
We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
reStructuredText
Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file 'mydoc.rst':
Terminal> doconce format rst mydoc.do.txt
We may now produce various other formats:
Terminal> rst2html.py mydoc.rst > mydoc.html # html Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
The OpenOffice file 'mydoc.odt' can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program 'unovonv' to convert between the many formats OpenOffice supports *on the command line*. Run
Terminal> unoconvshow

```
tutorial.pnd
to see all the formats that are supported.
For example, the following commands take
'mydoc.odt' to Microsoft Office Open XML format,
classic MS Word format, and PDF:
~~~~~~~~~~~~~~{.Bash}
Terminal> unoconv -f ooxml mydoc.odt
Terminal > unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
*Remark about Mathematical Typesetting.* At the time of this writing, there is n
o easy way to go from Doconce
and LaTeX mathematics to reST and further to OpenOffice and the
"MS Word world". Mathematics is only fully supported by 'latex' as
output and to a wide extent also supported by the 'sphinx' output format.
Some links for going from LaTeX to Word are listed below.
 * <http://ubuntuforums.org/showthread.php?t=1033441>
 * <http://tug.org/utilities/texconv/textopc.html>
 * <http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html>
Sphinx
_____
Sphinx documents demand quite some steps in their creation. We have automated
most of the steps through the 'doconce sphinx_dir' command:
-----{.Bash}
Terminal> doconce sphinx_dir author="authors' names" \
         title="some title" version=1.0 dirname=sphinxdir \
         theme=mytheme file1 file2 file3 ...
The keywords 'author', 'title', and 'version' are used in the headings
of the Sphinx document. By default, 'version' is 1.0 and the script
will try to deduce authors and title from the doconce files 'filel',
'file2', etc. that together represent the whole document. Note that none of the individual Doconce files 'file1', 'file2', etc. should include the rest as their union makes up the whole document.
The default value of 'dirname' is 'sphinx-rootdir'. The 'theme'
keyword is used to set the theme for design of HTML output from
Sphinx (the default theme is ''default'').
With a single-file document in 'mydoc.do.txt' one often just runs
-----{.Bash}
Terminal > doconce sphinx_dir mydoc
and then an appropriate Sphinx directory 'sphinx-rootdir' is made with
relevant files.
The 'doconce sphinx_dir' command generates a script
```

'automake-sphinx.py' for compiling the Sphinx document into an HTML document. One can either run 'automake-sphinx.py' or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

Te 'doconce sphinx\_dir' script copies directories named 'figs' or 'figures' over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, 'automake-sphinx.py' must be edited accordingly.

Links to local files (not 'http:' or 'file:' URLs) must be placed in the '\_static' subdirectory of the Sphinx directory. The utility 'doconce sphinxfix\_localURLs' is run to check for local links: for each such link, say 'dirl/dir2/myfile.txt' it replaces the link by '\_static/myfile.txt' and copies 'dirl/dir2/myfile.txt' to a local '\_static' directory (in the same directory as the script is run). The user must copy all '\_static/\*' files to the '\_static' subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the '\_static' subdirectory of the Sphinx directory.

It may be wise to place relevant files in a '\_static' directory and link to these directly from the Doconce document - then links to not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the 'conf.py' configuration file for Sphinx is edited accordingly, and a script 'make-themes.sh' can make HTML documents with one or more themes. For example,

to realize the themes 'fenics' and 'pyramid', one writes

~~~~~~~~{.Bash} Terminal> ./make-themes.sh fenics pyramid

The resulting directories with HTML documents are '\_build/html\_fenics' and '\_build/html\_pyramid', respectively. Without arguments, 'make-themes.sh' makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file 'mydoc.do.txt'.

\*Step 1.\* Translate Doconce into the Sphinx format:

Terminal> doconce format sphinx mydoc

\*Step 2.\* Create a Sphinx root directory either manually or by using the interactive 'sphinx-quickstart'

program. Here is a scripted version of the steps with the latter:

~~~~~~{.Bash}
mkdir sphinx-rootdir
sphinx-quickstart <<EOF</pre>

```
tutorial.pnd
sphinx-rootdir
Name of My Sphinx Document
version
version
.rst
index
n
У
n
n
n
n
У
n
n
У
У
У
EOF
The autogenerated 'conf.py' file
may need some edits if you want to specific layout (Sphinx themes)
of HTML pages. The 'doconce sphinx_dir' generator makes an extended 'conv.py' file where, among other things, several useful Sphinx extensions
are included.
*Step 3.* Copy the 'mydoc.rst' file to the Sphinx root directory:
Terminal > cp mydoc.rst sphinx-rootdir
If you have figures in your document, the relative paths to those will
be invalid when you work with 'mydoc.rst' in the 'sphinx-rootdir'
directory. Either edit 'mydoc.rst' so that figure file paths are correct,
or simply copy your figure directories to 'sphinx-rootdir'. Links to local files in 'mydoc.rst' must be modified to links to
files in the '_static' directory, see comment above.
*Step 4.* Edit the generated 'index.rst' file so that 'mydoc.rst'
is included, i.e., add 'mydoc' to the 'toctree' section so that it becomes
.. toctree::
  :maxdepth: 2
  mydoc
(The spaces before 'mydoc' are important!)
*Step 5.* Generate, for instance, an HTML version of the Sphinx source:
 ~~~~~~~~~{.Bash}
```

make clean # remove old versions
make html

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with 'index.html' files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

\*Step 6.\* View the result:

~~~~~~~{.Bash}

Terminal> firefox \_build/html/index.html

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows '!bc': 'cod' gives Python ('code-block:: python' in Sphinx syntax) and 'cppcod' gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

#### Google Code Wiki

\_\_\_\_\_

There are several different wiki dialects, but Doconce only support the one used by Google Code (http://code.google.com/p/support/wiki/WikiSyntax). The transformation to this format, called 'gwiki' to explicitly mark it as the Google Code dialect, is done by

Terminal> doconce format gwiki mydoc.do.txt

You can then open a new wiki page for your Google Code project, copy the 'mydoc.gwiki' output file from 'doconce format' and paste the file contents into the wiki page. Press \_Preview\_ or \_Save Page\_ to see the formatted result.

When the Doconce file contains figures, each figure filename must be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the '.rst' file is going to be filtered to LaTeX or HTML, it cannot know if '.eps' or '.png' is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final

```
tutorial.pnd
format(s). The 'make.sh' files in 'docs/manual' and 'docs/tutorial'
constitute comprehensive examples on how such scripts can be made.
Demos
The current text is generated from a Doconce format stored in the file
docs/tutorial/tutorial.do.txt
The file 'make.sh' in the 'tutorial' directory of the
Doconce source code contains a demo of how to produce a variety of
formats. The source of this tutorial, 'tutorial.do.txt' is the starting point. Running 'make.sh' and studying the various generated files and comparing them with the original 'tutorial.do.txt' file,
gives a quick introduction to how Doconce is used in a real case.
[Here](https://doconce.googlecode.com/hg/doc/demos/tutorial/index.html)
is a sample of how this tutorial looks in different formats.
There is another demo in the 'docs/manual' directory which
translates the more comprehensive documentation, 'manual.do.txt', to
various formats. The 'make.sh' script runs a set of translations.
Dependencies and Installation
Doconce itself is pure Python code hosted at <a href="http://code.google.com/p/doconce">http://code.google.com/p/doconce</a>.
  Its installation from the
Mercurial ('hg') source follows the standard procedure:
~~~~~~~~~~~~~~~~{.Bash}
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
If you make use of the [Preprocess](http://code.google.com/p/preprocess)
preprocessor, this program must be installed:
       svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
      A much more advanced alternative to Preprocess is
[Mako](http://www.makotemplates.org). Its installation is most
conveniently done by 'pip',
pip install Mako
```

```
tutorial.pnd
This command requires 'pip' to be installed. On Debian Linux systems,
such as Ubuntu, the installation is simply done by
~~~~~~~~~~~~~~~~{.Bash}
sudo apt-get install python-pip
Alternatively, one can install from the 'pip' [source code](http://pypi.python.o
rg/pypi/pip).
To make LaTeX
documents (without going through the reStructuredText format) you
need [ptex2tex](http://code.google.com/p/ptex2tex), which is
installed by
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
As seen, 'cp2texmf.sh' copies some special stylefiles that
that 'ptex2tex' potentially makes use of. Some more standard stylefiles are also needed. These are installed by
sudo apt-get install texlive-latex-extra
on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with
the necessary stylefiles (if not, they can be found by googling and installed
manually in the '~/texmf/tex/latex/misc' directory).
The *minted* LaTeX style is offered by 'ptex2tex' and popular among
users. This style requires the package [Pygments](http://pygments.org):
-----{.Bash}
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
If you use the minted style, you have to enable it by running 'ptex2tex -DMINTED' and then 'latex -shell-escape', see
the the section [From Doconce to Other Formats](#s).
For 'rst' output and further transformation to LaTeX, HTML, XML,
OpenOffice, and so on, one needs [docutils](http://docutils.sourceforge.net).
The installation can be done by
~~~~~~~~{.Bash}
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
cd docutils
sudo python setup.py install
```

```
tutorial.pnd
cd ..
To use the OpenOffice suite you will typically on Debian systems install
~~~~~~~~~~~~~~~~~{.Bash}
sudo apt-get install unovonv libreoffice libreoffice-dmaths
There is a possibility to create PDF files from reST documents
using ReportLab instead of LaTeX. The enabling software is
[rst2pdf](http://code.google.com/p/rst2pdf). Either download the tarball or clone the svn repository, go to the `rst2pdf` directory and
run 'sudo python setup.py install'.
Output to 'sphinx' requires of course [Sphinx](http://sphinx.pocoo.org),
installed by
-----{.Bash}
hg clone https://bitbucket.org/birkenfeld/sphinx
sudo python setup.py install
        When the output format is 'epydoc' one needs that program too, installed
~~~~~~~~~~~~~~~~~~{.Bash}
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ..
Finally, translation to 'pandoc' requires the
[Pandoc](http://johnmacfarlane.net/pandoc/) program
(written in Haskell) to be installed.
  sudo apt-get install pandoc
*Remark.* Several of the packages above installed from source code
are also available in Debian-based system through the
'apt-get install' command. However, we recommend installation directly
from the version control system repository as there might be important
updates and bug fixes. For 'svn' directories, go to the directory, run 'svn update', and then 'sudo python setup.py install'. For Mercurial ('hg') directories, go to the directory, run
'hg pull; hg update', and then 'sudo python setup.py install'.
Doconce itself is frequently updated so these commands should be
run regularly.
```

# DOCONCE: DOCUMENT ONCE, INCLUDE ANYWHERE

Author Hans Petter Langtangen

**Date** Mar 11, 2012

- When writing a note, report, manual, etc., do you find it difficult to choose the typesetting format? That is, to choose between plain (email-like) text, wiki, Word/OpenOffice, LaTeX, HTML, reStructuredText, Sphinx, XML, etc. Would it be convenient to start with some very simple text-like format that easily converts to the formats listed above, and then at some later stage eventually go with a particular format?
- Do you need to write documents in varying formats but find it difficult to remember all the typesetting details of various formats like LaTeX, HTML, reStructuredText, Sphinx, and wiki? Would it be convenient to generate the typesetting details of a particular format from a very simple text-like format with minimal tagging?
- Do you have the same information scattered around in different documents in different typesetting formats? Would it be a good idea to write things once, in one format, stored in one place, and include it anywhere?

If any of these questions are of interest, you should keep on reading.

## THE DOCONCE CONCEPT

#### Doconce is two things:

- 1. Doconce is a very simple and minimally tagged markup language that looks like ordinary ASCII text (much like what you would use in an email), but the text can be transformed to numerous other formats, including HTML, Pandoc, Google wiki, LaTeX, PDF, reStructuredText (reST), Sphinx, Epytext, and also plain text (where non-obvious formatting/tags are removed for clear reading in, e.g., emails). From reST you can (via rst2\* programs) go to XML, HTML, LaTeX, PDF, OpenOffice, and from the latter (via unoconv) to RTF, numerous MS Word formats (including MS Office Open XML), DocBook, PDF, MediaWiki, XHTML. From Pandoc one can generate Markdown, reST, LaTeX, HTML, PDF, DocBook XML, OpenOffice, GNU Texinfo, MediaWiki, RTF, Groff, and other formats.
- 2. Doconce is a working strategy for never duplicating information. Text is written in a single place and then transformed to a number of different destinations of diverse type (software source code, manuals, tutorials, books, wikis, memos, emails, etc.). The Doconce markup language support this working strategy. The slogan is: "Write once, include anywhere".

#### Here are some Doconce features:

- Doconce markup does include tags, so the format is more tagged than Markdown and Pandoc, but less than reST, and very much less than LaTeX and HTML.
- Doconce can be converted to plain untagged text, often desirable for computer programs and email.
- Doconce has good support for copying in parts of computer code, say in examples, directly from the source code files
- Doconce has full support for LaTeX math, and integrates very well with big LaTeX projects (books).
- Doconce is almost self-explanatory and is a handy starting point for generating documents in more complicated
  markup languages, such as Google wiki, LaTeX, and Sphinx. A primary application of Doconce is just to make
  the initial versions of a Sphinx or wiki document.
- Contrary to the similar Pandoc translator, Doconce integrates with Sphinx and Google wiki. However, if these formats are not of interest, Pandoc is obviously a superior tool.

#### Doconce was particularly written for the following sample applications:

- Large books written in LaTeX, but where many pieces (computer demos, projects, examples) can be written in Doconce to appear in other contexts in other formats, including plain HTML, Sphinx, wiki, or MS Word.
- Software documentation, primarily Python doc strings, which one wants to appear as plain untagged text for viewing in Pydoc, as reStructuredText for use with Sphinx, as wiki text when publishing the software at web sites, and as LaTeX integrated in, e.g., a thesis.
- Quick memos, which start as plain text in email, then some small amount of Doconce tagging is added, before the memos can appear as Sphinx web pages, MS Word documents, or in wikis.

History: Doconce was developed in 2006 at a time when most popular markup languages used quite some tagging. Later, almost untagged markup languages like Markdown and Pandoc became popular. Doconce is not a replacement of Pandoc, which is a considerably more sophisticated project. Moreover, Doconce was developed mainly to fulfill the needs for a flexible source code base for books with much mathematics and computer code.

Disclaimer: Doconce is a simple tool, largely based on interpreting and handling text through regular expressions. The possibility for tweaking the layout is obviously limited since the text can go to all sorts of sophisticated markup languages. Moreover, because of limitations of regular expressions, some formatting of Doconce syntax may face problems when transformed to HTML, LaTeX, Sphinx, and similar formats.

## WHAT DOES DOCONCE LOOK LIKE?

Doconce text looks like ordinary text, but there are some almost invisible text constructions that allow you to control the formating. Here are som examples.

- Bullet lists arise from lines starting with an asterisk.
- Emphasized words are surrounded by asterisks.
- Words in boldface are surrounded by underscores.
- Words from computer code are enclosed in back quotes and then typeset verbatim (in a monospace font).
- Section headings are recognied by equality (=) signs before and after the title, and the number of = signs indicates the level of the section: 7 for main section, 5 for subsection, and 3 for subsubsection.
- Paragraph headings are recognized by a double underscore before and after the heading.
- The abstract of a document starts with *Abstract* as paragraph heading, and all text up to the next heading makes up the abstract,
- Blocks of computer code can easily be included by placing !bc (begin code) and !ec (end code) commands at separate lines before and after the code block.
- Blocks of computer code can also be imported from source files.
- Blocks of LaTeX mathematics can easily be included by placing !bt (begin TeX) and !et (end TeX) commands at separate lines before and after the math block.
- There is support for both LaTeX and text-like inline mathematics.
- Figures and movies with captions, simple tables, URLs with links, index list, labels and references are supported.
- Invisible comments in the output format can be inserted throughout the text.
- Visible comments can be inserted so that authors and readers can comment upon the text (and at any time turn on/off output of such comments).
- There is special support for advanced exercises features.
- With a simple preprocessor, Preprocess or Mako, one can include other documents (files) and large portions of text can be defined in or out of the text.
- With the Mako preprocessor one can even embed Python code and use this to steer generation of Doconce text.

Here is an example of some simple text written in the Doconce format:

```
==== A Subsection with Sample Text =====
label{my:first:sec}
```

```
Ordinary text looks like ordinary text, and the tags used for
_boldface_ words, *emphasized* words, and 'computer' words look
natural in plain text. Lists are typeset as you would do in an email,
  * item 1
  * item 2
  * item 3
Lists can also have automatically numbered items instead of bullets,
 o item 1
 o item 2
 o item 3
URLs with a link word are possible, as in "hpl": "http://folk.uio.no/hpl".
If the word is URL, the URL itself becomes the link name,
as in "URL": "tutorial.do.txt".
References to sections may use logical names as labels (e.g., a
"label" command right after the section title), as in the reference to
Section ref{my:first:sec}.
Doconce also allows inline comments such as [hpl: here I will make
some remarks to the text] for allowing authors to make notes. Inline
comments can be removed from the output by a command-line argument
(see Section ref{doconce2formats} for an example).
```

Tables are also supperted, e.g.,

# lines beginning with # are comment lines

The Doconce text above results in the following little document:

### 3.1 A Subsection with Sample Text

Ordinary text looks like ordinary text, and the tags used for **boldface** words, *emphasized* words, and computer words look natural in plain text. Lists are typeset as you would do in an email,

- item 1
- item 2
- item 3

Lists can also have numbered items instead of bullets, just use an ○ (for ordered) instead of the asterisk:

- 1. item 1
- 2. item 2
- 3. item 3

URLs with a link word are possible, as in hpl. If the word is URL, the URL itself becomes the link name, as in tutorial do.txt.

References to sections may use logical names as labels (e.g., a "label" command right after the section title), as in the reference to the section A Subsection with Sample Text.

Doconce also allows inline comments such as (**hpl**: here I will make some remarks to the text) for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see the section *From Doconce to Other Formats* for an example).

Tables are also supperted, e.g.,

| time | velocity | acceleration |
|------|----------|--------------|
| 0.0  | 1.4186   | -5.01        |
| 2.0  | 1.376512 | 11.919       |
| 4.0  | 1.1E+1   | 14.717624    |

### 3.2 Mathematics and Computer Code

Inline mathematics, such as  $\nu = \sin(x)$ , allows the formula to be specified both as LaTeX and as plain text. This results in a professional LaTeX typesetting, but in other formats the text version normally looks better than raw LaTeX mathematics with backslashes. An inline formula like  $\nu = \sin(x)$  is typeset as

```
\alpha = \sin(x) = \sin(x)
```

The pipe symbol acts as a delimiter between LaTeX code and the plain text version of the formula.

Blocks of mathematics are better typeset with raw LaTeX, inside !bt and !et (begin tex / end tex) instructions. The result looks like this:

$$\begin{split} \frac{\partial u}{\partial t} &= \nabla^2 u + f, \\ \frac{\partial v}{\partial t} &= \nabla \cdot (q(u)\nabla v) + g \end{split} \tag{3.1}$$

Of course, such blocks only looks nice in LaTeX. The raw LaTeX syntax appears in all other formats (but can still be useful for those who can read LaTeX syntax).

You can have blocks of computer code, starting and ending with !bc and !ec instructions, respectively. Such blocks look like

```
from math import sin, pi
def myfunc(x):
    return sin(pi*x)

import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)
```

A code block must come after some plain sentence (at least for successful output to sphinx, rst, and ASCII-close formats), not directly after a section/paragraph heading or a table.

It is possible to add a specification of an environment for typesetting the verbatim code block, e.g., !bc xxx where xxx is an identifier like pycod for code snippet in Python, sys for terminal session, etc. When Doconce is filtered to LaTeX, these identifiers are used as in ptex2tex and defined in a configuration file .ptext2tex.cfg, while when filtering to Sphinx, one can have a comment line in the Doconce file for mapping the identifiers to legal language names for Sphinx (which equals the legal language names for Pygments):

# sphinx code-blocks: pycod=python cod=fortran cppcod=c++ sys=console

By default, pro and cod are python, sys is console, while xpro and xcod are computer language specific for x in f (Fortran), c (C), cpp (C++), pl (Perl), m (Matlab), sh (Unix shells), cy (Cython), and py (Python).

One can also copy computer code directly from files, either the complete file or specified parts. Computer code is then never duplicated in the documentation (important for the principle of avoiding copying information!). A complete file is typeset with !bc pro, while a part of a file is copied into a !bc cod environment. What pro and cod mean is then defined through a .ptex2tex.cfg file for LaTeX and a sphinx code-blocks comment for Sphinx.

Another document can be included by writing #include "mynote.do.txt" on a line starting with (another) hash sign. Doconce documents have extension do.txt. The do part stands for doconce, while the trailing .txt denotes a text document so that editors gives you the right writing environment for plain text.

# 3.3 Macros (Newcommands), Cross-References, Index, and Bibliography

Doconce supports a type of macros via a LaTeX-style newcommand construction. The newcommands defined in a file with name newcommand\_replace.tex are expanded when Doconce is filtered to other formats, except for LaTeX (since LaTeX performs the expansion itself). Newcommands in files with names newcommands.tex and newcommands\_keep.tex are kept unaltered when Doconce text is filtered to other formats, except for the Sphinx format. Since Sphinx understands LaTeX math, but not newcommands if the Sphinx output is HTML, it makes most sense to expand all newcommands. Normally, a user will put all newcommands that appear in math blocks surrounded by !bt and !et in newcommands\_keep.tex to keep them unchanged, at least if they contribute to make the raw LaTeX math text easier to read in the formats that cannot render LaTeX. Newcommands used elsewhere throughout the text will usually be placed in newcommands\_replace.tex and expanded by Doconce. The definitions of newcommands in the newcommands\*.tex files must appear on a single line (multi-line newcommands are too hard to parse with regular expressions).

Recent versions of Doconce also offer cross referencing, typically one can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the doc/manual/manual.do.txt file (see the demo page for various formats of this document).

## FROM DOCONCE TO OTHER FORMATS

Transformation of a Doconce document mydoc.do.txt to various other formats applies the script doconce format:

Terminal> doconce format format mydoc.do.txt

#### or just

Terminal> doconce format format mydoc

The make or preprocess programs are always used to preprocess the file first, and options to make or preprocess can be added after the filename. For example,

```
Terminal> doconce format latex mydoc -Dextra_sections -DVAR1=5  # preprocess Terminal> doconce format latex yourdoc extra_sections=True VAR1=5  # mako
```

The variable FORMAT is always defined as the current format when running preprocess. That is, in the last example, FORMAT is defined as latex. Inside the Doconce document one can then perform format specific actions through tests like #if FORMAT == "latex".

Inline comments in the text are removed from the output by

```
Terminal> doconce format latex mydoc --skip_inline_comments
```

One can also remove all such comments from the original Doconce file by running:

```
Terminal > doconce remove_inline_comments mydoc
```

This action is convenient when a Doconce document reaches its final form and comments by different authors should be removed.

#### **4.1 HTML**

Making an HTML version of a Doconce file mydoc.do.txt is performed by

```
Terminal> doconce format html mydoc
```

The resulting file mydoc.html can be loaded into any web browser for viewing.

#### 4.2 Pandoc

Output in the versatile Pandoc format results from

Terminal> doconce format pandoc mydoc

The name of the output file is mydoc.pnd. From this format one can go to numerous other formats:

```
Terminal> pandoc -R -t markdown -o mydoc.txt mydoc.pnd Terminal> pandoc -R -t mediawiki -o mydoc.mwk mydoc.pnd
```

Pandoc supports latex, html, odt (OpenOffice), docx (Microsoft Word), rtf, texinfo, to mention some. The -R option makes Pandoc pass raw HTML or LaTeX to the output format instead of ignoring it. See the Pandoc documentation for the many features of the pandoc program.

#### 4.3 LaTeX

Making a LaTeX file mydoc.tex from mydoc.do.txt is done in two steps: .. Note: putting code blocks inside a list is not successful in many

#### Step 1. Filter the doconce text to a pre-LaTeX form mydoc.p.tex for ptex2tex:

```
Terminal> doconce format latex mydoc
```

LaTeX-specific commands ("newcommands") in math formulas and similar can be placed in files newcommands.tex, newcommands\_keep.tex, or newcommands\_replace.tex (see the section *Macros* (*Newcommands*), *Cross-References*, *Index*, *and Bibliography*). If these files are present, they are included in the LaTeX document so that your commands are defined.

Step 2. Run ptex2tex (if you have it) to make a standard LaTeX file,

Terminal> ptex2tex mydoc

or just perform a plain copy,

Terminal> cp mydoc.p.tex mydoc.tex

Doconce generates a .p.tex file with some preprocessor macros that can be used to steer certain properties of the LaTeX document. For example, to turn on the Helvetica font instead of the standard Computer Modern font, run

```
Terminal> ptex2tex -DHELVETICA mydoc
```

The title, authors, and date are by default typeset in a non-standard way to enable a nicer treatment of multiple authors having institutions in common. However, the standard LaTeX "maketitle" heading is also available through

```
Terminal> ptex2tex -DLATEX_HEADING=traditional mydoc
```

#### A separate titlepage can be generate by

```
Terminal> ptex2tex -DLATEX_HEADING=titlepage mydoc
```

The ptex2tex tool makes it possible to easily switch between many different fancy formattings of computer or verbatim code in LaTeX documents. After any !bc command in the Doconce source you can insert verbatim block styles as defined in your .ptex2tex.cfg file, e.g., !bc cod for a code snippet, where cod is set to a certain environment in .ptex2tex.cfg (e.g., CodeIntended). There are over 30 styles to choose from.

Step 2b (optional). Edit the mydoc.tex file to your needs. For example, you may want to substitute section by section\* to avoid numbering of sections, you may want to insert linebreaks (and perhaps space) in the title, etc. This can be automatically edited with the aid of the doconce replace and doconce subst commands. The former works with substituting text directly, while the latter performs substitutions using regular expressions. Here are some examples:

```
Terminal> doconce replace 'section{' 'section*{' mydoc.tex Terminal> doconce subst 'title\{(.+)Using (.+)\}' \ 'title{\g<1> \\\ [1.5mm] Using \g<2>' mydoc.tex
```

A lot of tailored fixes to the LaTeX document can be done by an appropriate set of text replacements and regular expression substitutions. You are anyway encourged to make a script for generating PDF from the LaTeX file.

Step 3. Compile mydoc.tex and create the PDF file:

```
Terminal> latex mydoc
Terminal> latex mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> latex mydoc
Terminal> dvipdf mydoc
```

If one wishes to use the Minted\_Python, Minted\_Cpp, etc., environments in ptex2tex for typesetting code (specified, e.g., in the \*pro and \*cod environments in .ptex2tex.cfg or \$HOME/.ptex2tex.cfg), the minted LaTeX package is needed. This package is included by running doconce format with the -DMINTED option:

```
Terminal> ptex2tex -DMINTED mydoc
```

In this case, latex must be run with the -shell-escape option:

```
Terminal> latex -shell-escape mydoc
Terminal> latex -shell-escape mydoc
Terminal> makeindex mydoc # if index
Terminal> bibitem mydoc # if bibliography
Terminal> latex -shell-escape mydoc
Terminal> dvipdf mydoc
```

#### 4.4 PDFLaTeX

Running pdflatex instead of latex follows almost the same steps, but the start is

```
Terminal> doconce format latex mydoc
```

Then ptex2tex is run as explained above, and finally

```
Terminal> pdflatex -shell-escape mydoc
Terminal> makeindex mydoc  # if index
Terminal> bibitem mydoc  # if bibliography
Terminal> pdflatex -shell-escape mydoc
```

#### 4.5 Plain ASCII Text

We can go from Doconce "back to" plain untagged text suitable for viewing in terminal windows, inclusion in email text, or for insertion in computer source code:

```
Terminal> doconce format plain mydoc.do.txt # results in mydoc.txt
```

4.4. PDFLaTeX

### 4.6 reStructuredText

Going from Doconce to reStructuredText gives a lot of possibilities to go to other formats. First we filter the Doconce text to a reStructuredText file mydoc.rst:

```
Terminal> doconce format rst mydoc.do.txt
```

We may now produce various other formats:

```
Terminal> rst2html.py mydoc.rst > mydoc.html # html
Terminal> rst2latex.py mydoc.rst > mydoc.tex # latex
Terminal> rst2xml.py mydoc.rst > mydoc.xml # XML
Terminal> rst2odt.py mydoc.rst > mydoc.odt # OpenOffice
```

The OpenOffice file mydoc.odt can be loaded into OpenOffice and saved in, among other things, the RTF format or the Microsoft Word format. However, it is more convenient to use the program unovonv to convert between the many formats OpenOffice supports on the command line. Run

```
Terminal> unoconv --show
```

to see all the formats that are supported. For example, the following commands take mydoc.odt to Microsoft Office Open XML format, classic MS Word format, and PDF:

```
Terminal> unoconv -f ooxml mydoc.odt
Terminal> unoconv -f doc mydoc.odt
Terminal> unoconv -f pdf mydoc.odt
```

Remark about Mathematical Typesetting. At the time of this writing, there is no easy way to go from Doconce and LaTeX mathematics to reST and further to OpenOffice and the "MS Word world". Mathematics is only fully supported by latex as output and to a wide extent also supported by the sphinx output format. Some links for going from LaTeX to Word are listed below.

- http://ubuntuforums.org/showthread.php?t=1033441
- http://tug.org/utilities/texconv/textopc.html
- http://nileshbansal.blogspot.com/2007/12/latex-to-openofficeword.html

### 4.7 Sphinx

Sphinx documents demand quite some steps in their creation. We have automated most of the steps through the doconce sphinx\_dir command:

The keywords author, title, and version are used in the headings of the Sphinx document. By default, version is 1.0 and the script will try to deduce authors and title from the doconce files file1, file2, etc. that together represent the whole document. Note that none of the individual Doconce files file1, file2, etc. should include the rest as their union makes up the whole document. The default value of dirname is sphinx-rootdir. The theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is 'default').

With a single-file document in mydoc.do.txt one often just runs

```
Terminal> doconce sphinx_dir mydoc
```

and then an appropriate Sphinx directory sphinx-rootdir is made with relevant files.

The doconce sphinx\_dir command generates a script automake-sphinx.py for compiling the Sphinx document into an HTML document. One can either run automake-sphinx.py or perform the steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.

Te doconce sphinx\_dir script copies directories named figs or figures over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, automake-sphinx.py must be edited accordingly. Links to local files (not http: or file: URLs) must be placed in the \_static subdirectory of the Sphinx directory. The utility doconce sphinxfix\_localURLs is run to check for local links: for each such link, say dir1/dir2/myfile.txt it replaces the link by \_static/myfile.txt and copies dir1/dir2/myfile.txt to a local \_static directory (in the same directory as the script is run). The user must copy all \_static/\* files to the \_static subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the \_static subdirectory of the Sphinx directory. It may be wise to place relevant files in a \_static directory and link to these directly from the Doconce document - then links to not need to be modified when creating a Sphinx version of the document.

Doconce comes with a collection of HTML themes for Sphinx documents. These are packed out in the Sphinx directory, the <code>conf.py</code> configuration file for Sphinx is edited accordingly, and a script <code>make-themes.sh</code> can make HTML documents with one or more themes. For example, to realize the themes <code>fenics</code> and <code>pyramid</code>, one writes

```
Terminal> ./make-themes.sh fenics pyramid
```

The resulting directories with HTML documents are \_build/html\_fenics and \_build/html\_pyramid, respectively. Without arguments, make-themes.sh makes all available themes (!).

If it is not desirable to use the autogenerated scripts explained above, here is the complete manual procedure of generating a Sphinx document from a file mydoc.do.txt.

Step 1. Translate Doconce into the Sphinx format:

```
Terminal> doconce format sphinx mydoc
```

Step 2. Create a Sphinx root directory either manually or by using the interactive sphinx-quickstart program. Here is a scripted version of the steps with the latter:

```
mkdir sphinx-rootdir
sphinx-quickstart <<EOF
sphinx-rootdir
n
__
Name of My Sphinx Document
Author
version
version
.rst
index
n
y
n
n
n
n
n</pre>
```

4.7. Sphinx 15

n n y y y EOF

The autogenerated <code>conf.py</code> file may need some edits if you want to specific layout (Sphinx themes) of HTML pages. The <code>doconce sphinx\_dir</code> generator makes an extended <code>conv.py</code> file where, among other things, several useful Sphinx extensions are included.

Step 3. Copy the mydoc.rst file to the Sphinx root directory:

```
Terminal> cp mydoc.rst sphinx-rootdir
```

If you have figures in your document, the relative paths to those will be invalid when you work with mydoc.rst in the sphinx-rootdir directory. Either edit mydoc.rst so that figure file paths are correct, or simply copy your figure directories to sphinx-rootdir. Links to local files in mydoc.rst must be modified to links to files in the \_static directory, see comment above.

Step 4. Edit the generated index.rst file so that mydoc.rst is included, i.e., add mydoc to the toctree section so that it becomes

```
.. toctree::
   :maxdepth: 2
   mydoc
```

(The spaces before mydoc are important!)

Step 5. Generate, for instance, an HTML version of the Sphinx source:

```
make clean  # remove old versions
make html
```

Sphinx can generate a range of different formats: standalone HTML, HTML in separate directories with index.html files, a large single HTML file, JSON files, various help files (the qthelp, HTML, and Devhelp projects), epub, LaTeX, PDF (via LaTeX), pure text, man pages, and Texinfo files.

Step 6. View the result:

```
Terminal> firefox _build/html/index.html
```

Note that verbatim code blocks can be typeset in a variety of ways depending the argument that follows !bc: cod gives Python (code-block:: python in Sphinx syntax) and cppcod gives C++, but all such arguments can be customized both for Sphinx and LaTeX output.

### 4.8 Google Code Wiki

There are several different wiki dialects, but Doconce only support the one used by Google Code. The transformation to this format, called <code>gwiki</code> to explicitly mark it as the Google Code dialect, is done by

```
Terminal > doconce format gwiki mydoc.do.txt
```

You can then open a new wiki page for your Google Code project, copy the mydoc.gwiki output file from doconce format and paste the file contents into the wiki page. Press **Preview** or **Save Page** to see the formatted result.

When the Doconce file contains figures, each figure filename must be replaced by a URL where the figure is available. There are instructions in the file for doing this. Usually, one performs this substitution automatically (see next section).

### 4.9 Tweaking the Doconce Output

Occasionally, one would like to tweak the output in a certain format from Doconce. One example is figure filenames when transforming Doconce to reStructuredText. Since Doconce does not know if the .rst file is going to be filtered to LaTeX or HTML, it cannot know if .eps or .png is the most appropriate image filename. The solution is to use a text substitution command or code with, e.g., sed, perl, python, or scitools subst, to automatically edit the output file from Doconce. It is then wise to run Doconce and the editing commands from a script to automate all steps in going from Doconce to the final format(s). The make.sh files in docs/manual and docs/tutorial constitute comprehensive examples on how such scripts can be made.

### **4.10 Demos**

The current text is generated from a Doconce format stored in the file

```
docs/tutorial/tutorial.do.txt
```

The file make.sh in the tutorial directory of the Doconce source code contains a demo of how to produce a variety of formats. The source of this tutorial, tutorial.do.txt is the starting point. Running make.sh and studying the various generated files and comparing them with the original tutorial.do.txt file, gives a quick introduction to how Doconce is used in a real case. Here is a sample of how this tutorial looks in different formats.

There is another demo in the docs/manual directory which translates the more comprehensive documentation, manual.do.txt, to various formats. The make.sh script runs a set of translations.

### 4.11 Dependencies and Installation

Doconce itself is pure Python code hosted at http://code.google.com/p/doconce. Its installation from the Mercurial (hg) source follows the standard procedure:

```
# Doconce
hg clone https://doconce.googlecode.com/hg/ doconce
cd doconce
sudo python setup.py install
cd ..
```

If you make use of the Preprocess preprocessor, this program must be installed:

```
svn checkout http://preprocess.googlecode.com/svn/trunk/ preprocess
cd preprocess
cd doconce
sudo python setup.py install
cd ..
```

A much more advanced alternative to Preprocess is Mako. Its installation is most conveniently done by pip,

```
pip install Mako
```

This command requires pip to be installed. On Debian Linux systems, such as Ubuntu, the installation is simply done by

```
sudo apt-get install python-pip
```

Alternatively, one can install from the pip source code.

To make LaTeX documents (without going through the reStructuredText format) you need ptex2tex, which is installed by

```
svn checkout http://ptex2tex.googlecode.com/svn/trunk/ ptex2tex
cd ptex2tex
sudo python setup.py install
cd latex
sh cp2texmf.sh # copy stylefiles to ~/texmf directory
cd ../..
```

As seen, cp2texmf.sh copies some special stylefiles that that ptex2tex potentially makes use of. Some more standard stylefiles are also needed. These are installed by

```
sudo apt-get install texlive-latex-extra
```

on Debian Linux (including Ubuntu) systems. TeXShop on Mac comes with the necessary stylefiles (if not, they can be found by googling and installed manually in the ~/texmf/tex/latex/misc directory).

The minted LaTeX style is offered by ptex2tex and popular among users. This style requires the package Pygments:

```
hg clone ssh://hg@bitbucket.org/birkenfeld/pygments-main pygments
cd pygments
sudo python setup.py install
```

If you use the minted style, you have to enable it by running ptex2tex -DMINTED and then latex -shell-escape, see the the section *From Doconce to Other Formats*.

For rst output and further transformation to LaTeX, HTML, XML, OpenOffice, and so on, one needs docutils. The installation can be done by

```
svn checkout http://docutils.svn.sourceforge.net/svnroot/docutils/trunk/docutils
cd docutils
sudo python setup.py install
cd ..
```

To use the OpenOffice suite you will typically on Debian systems install

```
sudo apt-get install unovonv libreoffice libreoffice-dmaths
```

There is a possibility to create PDF files from reST documents using ReportLab instead of LaTeX. The enabling software is rst2pdf. Either download the tarball or clone the svn repository, go to the rst2pdf directory and run sudo python setup.py install.

Output to sphinx requires of course Sphinx, installed by

```
hg clone https://bitbucket.org/birkenfeld/sphinx
cd sphinx
sudo python setup.py install
cd ..
```

When the output format is epydoc one needs that program too, installed by

```
svn co https://epydoc.svn.sourceforge.net/svnroot/epydoc/trunk/epydoc epydoc
cd epydoc
sudo make install
cd ..
```

Finally, translation to pandoc requires the Pandoc program (written in Haskell) to be installed.

```
sudo apt-get install pandoc
```

Remark. Several of the packages above installed from source code are also available in Debian-based system through the apt-get install command. However, we recommend installation directly from the version control system repository as there might be important updates and bug fixes. For svn directories, go to the directory, run svn update, and then sudo python setup.py install. For Mercurial (hg) directories, go to the directory, run hg pull; hg update, and then sudo python setup.py install. Doconce itself is frequently updated so these commands should be run regularly.

Lists are typeset as you would do in an email,

- \* item 1
- \* item 2
- \* item 3

Lists can also have automatically numbered items instead of bullets,

- o item 1
- o item 2

,,

" tutorial.xml '

o item 3

URLs with a link word are possible, as in "hpl":"http://folk.uio.no/hpl".

If the word is URL, the URL itself becomes the link name,

as in " URL" : " tutorial.do.txt".

References to sections may use logical names as labels (e.g., a " label" command right after the section title), as in the reference to Section ref{my:first:sec}.

Doconce also allows inline comments such as [hpl: here I will make some remarks to the text] for allowing authors to make notes. Inline comments can be removed from the output by a command-line argument (see Section ref{doconce2formats} for an example).

Tables are also supperted, e.g.,

| time | velocity | acceleration |  |
|------|----------|--------------|--|
| r    | r        | r            |  |
| 0.0  | 1.4186   | l -5.01      |  |
| 2.0  | 1.376512 | 11.919       |  |
| 4.0  | 1.1E+1   | 14.717624    |  |
|      |          |              |  |

# lines beginning with # are comment lines</literal\_block><paragraph>The Doconce

<title>Mathematics and Computer Code</title><paragraph>Inline mathematics, such
as v = \sin(x),
allows the formula to be specified both as LaTeX and as plain text.
This results in a professional LaTeX typesetting, but in other formats
the text version normally looks better than raw LaTeX mathematics with
backslashes. An inline formula like v = sin(x) is
typeset as:</paragraph><literal_block xml:space="preserve">$\nu = \sin(x)$|$v =
sin(x)$</literal_block><paragraph>The pipe symbol acts as a delimiter between La
TeX code and the plain text
version of the formula.</paragraph><paragraph>Blocks of mathematics are better t
ypeset with raw LaTeX, inside
<literal>!bt</literal> and <literal>!et</literal> (begin tex / end tex) instruct
ions.
The result looks like this:</paragraph><literal_block xml:space="preserve">\begi
n{eqnarray}
{\partial u\over\partial t} &=& \nabla^2 u + f, label{myeq1}\\
{\partial v\over\partial t} &=& \nabla\cdot(q(u)\nabla v) + g
\end{eqnarray}</literal_block><paragraph>Of course, such blocks only looks nice
in LaTeX. The raw
LaTeX syntax appears in all other formats (but can still be useful
for those who can read LaTeX syntax).
of computer code, starting and ending with
<literal>!bc</literal> and <literal>!ec</literal> instructions, respectively. Su
ch blocks look like:</paragraph><literal_block xml:space="preserve">from math im
port sin, pi
def myfunc(x):
   return sin(pi*x)
import integrate
I = integrate.trapezoidal(myfunc, 0, pi, 100)literal_block><paragraph>A code b
lock must come after some plain sentence (at least for successful
output to teral>sphinxliteral>, <literal>rst</literal>, and ASCII-close for
not directly after a section/paragraph heading or a table.</paragraph><paragraph
>It is possible to add a specification of an
environment for typesetting the verbatim code block, e.g., <literal>!bc xxx</lit
eral>
where teral>xxx</literal> is an identifier like <literal>pycod</literal> for
code snippet in Python,
<literal>sys</literal> for terminal session, etc. When Doconce is filtered to La
TeX,
these identifiers are used as in teral>ptex2texeliteral> and defined in a
configuration file literal>.ptext2tex.cfg/literal>, while when filtering
to Sphinx, one can have a comment line in the Doconce file for
mapping the identifiers to legal language names for Sphinx (which equals
the legal language names for Pygments):</paragraph><literal_block xml:space="pre
```

```

right writing environment for plain text.</paragraph><target refid="newcommands"/
></section><section ids="macros-newcommands-cross-references-index-and-bibliogra"
phy newcommands" names="macros\ (newcommands),\ cross-references,\ index,\ and\
bibliography newcommands"><title>Macros (Newcommands), Cross-References, Index,
and Bibliography</title><paragraph>Doconce supports a type of macros via a LaTeX
-style <emphasis>newcommand</emphasis>
              The newcommands defined in a file with name
<literal>newcommand_replace.tex</literal> are expanded when Doconce is filtered
other formats, except for LaTeX (since LaTeX performs the expansion
itself). Newcommands in files with names teral>newcommands.tex</literal> and
<literal>newcommands_keep.tex</literal> are kept unaltered when Doconce text is
filtered to other formats, except for the Sphinx format. Since Sphinx
understands LaTeX math, but not newcommands if the Sphinx output is
HTML, it makes most sense to expand all newcommands. Normally, a user
will put all newcommands that appear in math blocks surrounded by
<literal>!bt</literal> and <literal>!et</literal> in <literal>newcommands_keep.t
ex</literal> to keep them unchanged, at
least if they contribute to make the raw LaTeX math text easier to
read in the formats that cannot render LaTeX. Newcommands used
elsewhere throughout the text will usually be placed in
<literal>newcommands_replace.tex</literal> and expanded by Doconce.
                                                                     The definit
ions of
newcommands in the teral>newcommands*.texfiles <emphasis>must</emp

line (multi-line newcommands are too hard to parse with regular
expressions).</paragraph><paragraph>Recent versions of Doconce also offer cross
referencing, typically one
```

tutorial.xml can define labels below (sub)sections, in figure captions, or in equations, and then refer to these later. Entries in an index can be defined and result in an index at the end for the LaTeX and Sphinx formats. Citations to literature, with an accompanying bibliography in a file, are also supported. The syntax of labels, references, citations, and the bibliography closely resembles that of LaTeX, making it easy for Doconce documents to be integrated in LaTeX projects (manuals, books). For further details on functionality and syntax we refer to the teral>doc/manual/manual.do.txt</literal> file (see the <reference name="demo page" refuri="https://doconce.googlecode.com/hg/doc/demos/</pre> manual/index.html">demo page</reference><target ids="demo-page" names="demo\ pag e" refuri="https://doconce.googlecode.com/hg/doc/demos/manual/index.html"/> for various formats of this document). Example on including another Doconce file (using preprocess):</comment><target r efid="doconce2formats"/></section></section ids="from-doconce-to-otherformats doconce2formats" names="from\ doconce\ to\ other\ formats doconce2format s"><title>From Doconce to Other Formats</title><paragraph>Transformation of a Do conce document <literal>mydoc.do.txt</literal> to various other formats applies the script teral>doconce formateliteral>:</paragraph>teral l\_block xml:space="preserve">Terminal> doconce format format mydoc.do.txt teral\_block><paragraph>or just:</paragraph><literal\_block xml:space="preserve">T erminal&qt; doconce format format mydoc</literal block><paragraph>The teral>m ako</literal> or teral>preprocess</literal> programs are always used to prepr ocess the file first, and options to <literal>mako/literal> or <literal>preprocess/liter al> can be added after the filename. Sphinx</title><paragraph>Sphinx documents demand quite some steps in their creat
ion. We have automated
most of the steps through the teral>doconce sphinx_dir</literal> command:</pa
ragraph><literal_block xml:space="preserve">Terminal&gt; doconce sphinx_dir auth
or="authors' names" \
          title=" some title" version=1.0 dirname=sphinxdir \
          theme=mytheme file1 file2 file3 ...</literal_block><paragraph>The keyw
ords teral>author</literal>, teral>title</literal>, and teral>version
literal> are used in the headings
of the Sphinx document. By default, teral>version</literal> is 1.0 and the sc
```

### Printed by Hans Petter Langtangen tutorial.xml ript will try to deduce authors and title from the doconce files literal>file1</lite teral>file2</literal>, etc. that together represent the whole document. Note none of the individual Doconce files teral>file1teral>, teral>file2</l iteral>, etc. should include the rest as their union makes up the whole document. The default value of <literal>dirname is <literal>sphinx-rootdir/lite ral>. The teral>theme keyword is used to set the theme for design of HTML output from Sphinx (the default theme is teral>'default'h>With a single-file document in <literal>mydoc.do.txtliteral> one often just runs:preserve">Terminal> doconce sphinx \_dir mydoc</literal\_block><paragraph>and then an appropriate Sphinx directory iteral>sphinx-rootdir</literal> is made with relevant files.</paragraph><paragraph>The teral>doconce sphinx\_dir command generates a script <literal>automake-sphinx.py</literal> for compiling the Sphinx document into an HTML document. One can either run teral>automake-sphinx.py</literal> or perform t he steps in the script manually, possibly with necessary modifications. You should at least read the script prior to executing it to have some idea of what is done.</paragraph><paragraph>Te teral>doconce sphinx\_dir /literal> script copies directories named <literal>figs</literal> or <literal>fi gures</literal> over to the Sphinx directory so that figures are accessible in the Sphinx compilation. If figures or movies are located in other directories, teral>automake-sphinx.py</literal> must be edited accordingly. Links to local files (not <literal>http:</literal> or <literal>file:</literal> U RLs) must be placed in the teral>\_staticliteral> subdirectory of the Sphinx directory. The utility teral>doconce sphinxfix\_localURLs links: for each such link, say eral>dir1/dir2/myfile.txt</literal> it replac the link by <literal>\_static/myfile.txt</literal> and copies <literal>dir1/dir2/ myfile.txt</literal> to a local <literal>\_static</literal> directory (in the same directory as the script is run). The user must copy all teral> static/\*</literal> files to the teral> static/literal> subdirectory of the Sphinx directory. Links to local HTML files (say another Sphinx document) may present a problem if they link to other files: all necessary files must be correctly copied to the teral>\_staticliteral> subdirectory of the Sphinx directory. It may be wise to place relevant files in a teral>\_staticdirectory and link to these directly from the Doconce document - then links to not need to be modified when creating a Sphinx version of the document.</paragraph><paragraph>Doconce comes with a collection of HTML them es for Sphinx documents. These are packed out in the Sphinx directory, the teral>conf.py</literal> configuration file for Sphinx is edited accordingly, and a script <literal>make-themes.sh</literal> can make HTML documents with one or more theme s. For example, to realize the themes <literal>fenics/literal> and <literal>pyramid/literal>, one writes:</paragraph><literal\_block xml:space="preserve">Terminal&gt; ./make-t

hemes.sh fenics pyramidliteral\_block><paragraph>The resulting directories with

HTML documents are teral> build/html fenics</literal>

and and teral>\_build/html\_pyramid/literal>, respectively. Without arguments,

```
tutorial.xml
<literal>make-themes.sh</literal> makes all available themes (!)./paragraph><pa</pre>
